The fees for hospital attendance are as follows — Perpetual ticket, in one payment, £12, annual ticket, £6 6s , six months, £4 4s ; three months, £2 2s ; monthly, £1 1s Separate payments amounting to £12 12s entitle the student to a life ticket The appointments are as follows 1 Resident physicians and surgeons are appointed and live in the house free of charge The appointment is for six months, but may be renewed at the end of that period by special recommendation 2 Non-resident house physicians and surgeons and clinical assistants are appointed for six months The appointment may be renewed for a like period by special recommendation 3 Clerks and dressers are appointed by the physicians and surgeons These appointments are open to all students and junior practitioners holding hospital tickets 4. Assistants in the Pathological Department are appointed by the pathologist

Facilities are given in connexion with the Post-graduate Courses arranged by the Edinburgh University and the two Royal Colleges jointly

ROYAL HOSPITAL FOR SICK CHILDREN, Sciennes-road, Edinburgh —This hospital contains 120 beds, and is fitted with every modern improvement A fully equipped out-patient department (medical and surgical) is conducted daily in a building adjoining the hospital Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given from time to time throughout the year by the staff Students may enter at any time Post-graduate Courses of Lectures are held during the year Full particulars can be obtained from the Registrar at the hospital

EYE, EAR, AND THROAT INFIRMARY OF EDINBURGH (with which is incorporated the Edinburgh Eye Dispensary), 6, Cambridge-street, Lothian-road — Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for outdoor patients for Eye Diseases , Mondays, Thursdays, and Saturdays at 12 noon, and Tuesdays and Fridays at 4 P M for outdoor Ear, Nose, and Throat Patients Patients whose diseases require operations or extra care are accommodated in the house *(10 beds)* Practical Ophthalmoscopic Classes may be arranged, and Clinical Assistants are appointed from time to time

A post-graduate course in Diseases of the Ear, Nose and Throat is held each academic term, commencing in May, October and January, and continuing for six weeks The next course commences in October The class meets at 5 P M on Tuesdays and Fridays, and the instruction, which is practical, is supplemented by lantern demonstrations Secretary Mr J P Watson, W S , 32, Charlotte-square

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations Within certain limits instruction given by recognised medical schools and teachers may be accepted, but not less than one-half of the subjects other than clinical must be taken in this or some other recognised university, and at least two years of the course must be taken in Glasgow University Seven degrees, open both to men and women, are conferred M B and Ch B (always conjointly), M D and Ch M ; B Sc in Public Health ; D Sc. in Public Health , B Sc in Pharmacy , and Ph D in the Faculty of Medicine A Diploma in Public Health (D P H) is also granted

All information as regards the extent and standard of the Preliminary Examination may be obtained by application to the Secretary, Scottish Universities Entrance Board, 81, North street St Andrews

For the degrees of M B and Ch B. a curriculum of five years is required after registration as a medical student in the books of the General Medical Council The candidate must, during his curriculum, have attended a course or courses of instruction in each of the following subjects of study, extending over not less than the number of terms specified in each case and including such class examinations as may be prescribed in connexion with

Laboratory, Dentistry, and Electro-cardiographic Installation There is an excellent library The resident officers are a resident surgical officer, resident medical officer, and two house surgeons Pupils are allowed to witness the whole of the practice of the hospital and to be present at operations and have every opportunity of acquiring a practical knowledge of their profession. A course of Practical Pharmacy is given by the dispenser Fees on application Applications should be made to the Honorary Secretary of the Medical Committee In 1925, 3839 in-patients and 30,925 out-patients were treated, 3986 operations were performed in the theatres

WORCESTER GENERAL INFIRMARY, Worcester —This hospital has 132 beds Pupils are taken by members of the Honorary Medical and Surgical Staff Number of operations last year 1222 New X Ray and Electrical and Wolfram Arc Light, Ear, Nose and Throat, and Orthopædic Departments have been erected and are now in use Additional accommodation for the Honorary Staff and Out-patients and also an Outdoor Shelter in connexion with the Children's Ward have been built as a memorial to King Edward VII, and fire-escape staircases recently erected In-patients, 1635, out-patients, 4840 Secretary: Mr E J Holland

YORK COUNTY HOSPITAL, York —This hospital contains 170 beds There are balconies for outdoor treatment, two installations of X ray apparatus, electrotherapeutic and massage department, and clinical laboratory

A Venereal Diseases Clinic is held

SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (recognised by the UNIVERSITY OF LONDON) —The Pharmaceutical Society conducts examinations for registration as (*a*) Chemist and Druggist and (*b*) Pharmaceutical Chemist For registration as Chemist and Druggist the candidate must pass (i) the Preliminary Scientific Examination (subjects Chemistry, Physics, and Botany), and (ii) the Chemist and Druggist Qualifying Examination (subjects Pharmacognosy, Pharmacy, Pharmaceutical Chemistry, and Forensic Pharmacy) Fee for each examination, 6 guineas, for each subsequent examination after failure, 4 and 6 guineas respectively The advanced or Major Examination (for registration as Pharmaceutical Chemist) includes Botany, Chemistry, Physics, Practical Chemistry, and Materia Medica Fee, 3 guineas The last Major Examination will be held in July, 1928 The Pharmaceutical Chemist Qualifying Examination (for registration as Pharmaceutical Chemist) includes Botany, Chemistry, Pharmacognosy, Pharmacy, and Forensic Pharmacy Candidates must have passed the Preliminary Scientific Examination Fee, 12 guineas for each subsequent examination after failure, 6 guineas Courses of Instruction are given for the Chemist and Druggist Qualifying Examination, for the Major Examination (during the session 1926-27 only), and (two years' course) for the Pharmaceutical Chemist Qualifying Examination in conjunction with University College

An Intercollegiate, two years' course for the Final Examination for the degree of B Pharm of the University of London is also given in conjunction with University College Medical students are admitted to the lectures and laboratory work in any or all the courses Certificates of instruction in the School are received by the Conjoint Board of the Royal Colleges and by the University of London Graduates in Science may carry out the research work necessary for the thesis for the Ph D of the University of London in the Society's Research Laboratories

Application for admission to the school, or for further information, may be made to the Dean, Prof Greenish, 17, Bloomsbury-square, London, W.C 1

II —SCOTLAND

THE UNIVERSITIES.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz, Bachelor of Medicine (M B), Bachelor of Surgery (Ch B), Doctor of Medicine (M D), and Master of Surgery (Ch M) The degree of Bachelor of Surgery cannot be conferred on any person who does not at the same time obtain the degree of Bachelor of Medicine, and similarly the degree of Bachelor of Medicine is not conferred on any person who does not at the same time obtain the degree of Bachelor of Surgery

No one is admitted to the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* who has not been engaged in Medical and Surgical study for five years

Candidates for the degrees of M B and Ch B must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons They must have attended courses of instruction in Clinical Surgery and Clinical Medicine each of nine months, and courses of instruction in all the subsidiary subjects They must have attended a course of instruction in Clinical and Practical Midwifery and have personally conducted 12 cases of labour

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations have effect —Three of the five years of medical study must be spent in the University of Edinburgh The remaining two years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teacher as may be recognised for the purpose by the University Court

Women are admitted to graduation in medicine under the same conditions as men

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is £34 13s, and the proportion of this sum to be paid by a candidate at each division of the examination shall be as follows—viz For the First Division of the Examination (Botany, Zoology, Physics, and Chemistry), £9 9s, for the Second Division (Anatomy and Physiology), £7 7s; for the Third Division (Pathology and Materia Medica and Therapeutics), £6 6s, and for the Final Division (Surgery and Clinical Surgery, Medicine and Clinical Medicine, Midwifery, Clinical Midwifery, and Clinical Gynæcology, and Forensic Medicine and Public Health), £11 11s

Bachelors of Medicine and *Bachelors of Surgery* may proceed to the degrees of *Doctor of Medicine* and *Master of Surgery* after they have spent one year in the medical or surgical wards respectively of a hospital, or the Military or Naval Medical Services, or in scientific work bearing directly on their profession, or two years in practice In each case an examination must be passed and a thesis submitted for approval of the Faculty The fee to be paid for the degree of M D is £21, and the fee to be paid for the degree of Ch.M is £21

Post-graduate Instruction —Courses of instruction are given for the Degrees of B Sc and D Sc in Public Health and for the University Diplomas in Public Health, Tropical Medicine and Hygiene, Psychiatry and Radiology These Diplomas are open to approved registered practitioners as well as to graduates in Medicine and Surgery of the University The University also takes part in the Courses given under the auspices of the Edinburgh Post-Graduate Courses in

Medicine In the departments of the Faculty of Medicine provision is made for research by students of graduate standing In the University laboratories facilities will be provided for candidates for the Degree of Ph D whose applications to engage in research have been accepted by the Senatus

The University of Edinburgh is especially rich in scholarships and prizes in medical subjects Full particulars can be obtained from the Dean of the Medical Faculty

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh —The number of students varies much in the classes and subjects It is within the limit to say that about 1000 students avail themselves each session of the opportunity of attending the school The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of London, Edinburgh, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards

The practical classes and laboratories will open and the lectures commence on Oct 5th

In accordance with the statutes of the University of Edinburgh one-half of the qualifying classes required for graduation may be attended in this school The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University The whole education required for graduation at the University of London may be taken in this school

Special courses of instruction for dental students are also included in the curriculum of this school

The minimum cost of the education in this School of Medicine for the Triple Qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the Joint Examinations, is about £170, payment of which is distributed over the period of study

Post-graduate Courses are conducted in conjunction with the University

Further particulars regarding the school, also its calendar (price 6*d*) may be had on application to the Dean of the School, 11, Bristo-place, Edinburgh

---

In connexion with the University and Royal Colleges Post-Graduate Instruction is given each year, chiefly in the Summer Vacation (July–September) Special Courses are arranged for, and particulars may be had on application to the Hon Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh

Clinical Instruction —ROYAL INFIRMARY, Edinburgh —This hospital has 921 beds and 42 cots for children Courses of Clinical Medicine and Surgery are given by the physicians and surgeons to male and female students Special instruction is given on Diseases of Women, Physical Diagnosis, Diseases of the Skin, Diseases of the Eye, the Ear, the Larynx, and the Teeth Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, Throat and Nose, and the Skin, and also to cases of Incidental Delirium or Insanity There is also a large and complete Radiological Department Post-mortem examinations are conducted in the anatomical theatre by the pathologist and his assistants, who also give practical instruction in Pathological Anatomy and Histology

UNIVERSITY OF GLASGOW

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations Within certain limits instruction given by recognised medical schools and teachers may be accepted, but not less than one-half of the subjects other than clinical must be taken in this or some other recognised university, and at least two years of the course must be taken in Glasgow University Seven degrees, open both to men and women, are conferred · M B and Ch B (always conjointly), M D and Ch M , B Sc in Public Health ; D Sc in Public Health , B Sc in Pharmacy , and Ph D in the Faculty of Medicine A Diploma in Public Health (D P H) is also granted

All information as regards the extent and standard of the Preliminary Examination may be obtained by application to the Secretary, Scottish Universities Entrance Board, 81, North-street St Andrews

For the degrees of M B and Ch B a curriculum of five years is required after registration as a medical student in the books of the General Medical Council The candidate must, during his curriculum, have attended a course or courses of instruction in each of the following subjects of study, extending over not less than the number of terms specified in each case, and including such class examinations as may be prescribed in connexion with the several courses:—Chemistry (including Organic Chemistry), two terms with Practical Chemistry, one term; Physics (with practical work), one term, Botany (with practical work), one term, Zoology (with practical work) one term; Anatomy and Practical Anatomy, five terms, Physiology and Practical Physiology, three terms, Materia Medica and Therapeutics (together or separately), each subject one term; Pathology and Practical Pathology, three terms, Medical Jurisprudence and Public Health (together or separately), each subject, one term, Midwifery and Diseases peculiar to Women and to Infants, two terms, Surgery, two terms; Medicine, two terms Candidates must attend for at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine, and the student must have acted for six months as clerk in medical and dresser in surgical wards, and must have had six months' outdoor practice; he must also have attended a course of Mental Diseases and of Practical Pharmacy (25 meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least 20 cases of labour and the Practice of a Lying-in Hospital The University also requires further study in various special subjects

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry, the second comprising Anatomy and Physiology, the third comprising Materia Medica and Therapeutics and Pathology, and the fourth or final, comprising Medical Jurisprudence and Public Health, Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and the Diseases Peculiar to Women and to Infants

The degrees of M D (Doctor of Medicine) and Ch M. (Master of Surgery) are higher degrees in Medicine and Surgery respectively, and candidates (not under 24 years of age) who have previously obtained the double bachelorship may be admitted to either M D or Ch.M on completing the after course prescribed, including an examination in Clinical Medicine for M D. and an examination in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch M.

The higher degree of Doctor of Philosophy (Ph D) is also conferred in the Faculty of Medicine Candidates must already have obtained a degree (or equivalent diploma) from an approved University or College and must prosecute a course of special study or research for two or three years and give evidence of satisfactory progress A thesis must be presented for approval by the Senate on the recommendation of a Special Committee The candidate may be required to undergo an oral or other examination on the subject-matter of the thesis

Fees—The Examination Fees for M B and Ch B are £34 13*s* The class fee in each subject of the curriculum for M B and Ch B is £3 3*s*, £4 4*s*, or £6 6*s*, and the present fee for hospital attendance is £7 There is also an annual Matriculation Fee of £2 2*s* The fee for M D is £21, and for Ch M £21

The great majority of the students take their hospital course at the Western, Royal, and Victoria Infirmary, and at the district hospitals of the Glasgow Parish Council, where clinical instruction is given by professors of the University and others Clinical instruction on Fevers is given at Ruchill and Belvidere Hospitals, while special courses, largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Ear, the Throat and Nose, Dermatology, Ophthalmology, Venereal Diseases, Tuberculosis, Insanity, and Electro-diagnosis and Therapeutics Queen Margaret College, sometime conducted as a separate institution for the higher education of women, was made over to the University in 1892, and in it certain medical classes for women are conducted under lecturers appointed by the University Court

Post-graduate Medical Teaching—Organised Post-graduate Medical Teaching is available in Glasgow under the auspices of Glasgow Post-Graduate Medical Association This Association is representative of practically all the Teaching Institutions in Glasgow, and its business is managed by a Board of which the chairman is Principal Sir Donald MacAlister, and the vice-chairman Sir Hector C Cameron Weekly demonstrations for practitioners are given throughout the winter and spring, and comprehensive courses of instruction during the summer and autumn There is a General Medical and Surgical Course, during the last two weeks of August and the first two weeks of September This is a whole-time course and includes most of the subjects of interest to the general practitioner The forenoons are occupied with General Medicine and Surgical Diagnosis and Minor Surgery in the Royal Infirmary and in the Victoria Infirmary In the afternoons special subjects are dealt with in some of the special hospitals or in the special departments of the general hospitals—two subjects each afternoon. On the four Saturday forenoons Tuberculosis and Infectious Fevers are demonstrated at Ruchill Fever Hospital Arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year As such they work under the direct supervision of the physician or surgeon in charge, and carry out such detailed investigations as directed Further information may be obtained from Dr James Carslaw, Secretary

In this University Bursaries and Prizes to the annual amount of over £1000 are appropriated to students in the Medical Faculty, and there are also several Scholarships and Fellowships which may be held by medical students who have gone through the Arts course A full list will be found in the Calendar

THE ANDERSON COLLEGE OF MEDICINE Dumbarton-road, Glasgow, W 1—Courses are given which qualify for all the licensing boards and for the Universities of Oxford, Cambridge, London, Durham, Edinburgh, and Glasgow (the latter two under certain conditions) Candidates for the Licence in Dental Surgery can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica The courses special to Dentistry are conducted at the Dental Hospital, Glasgow

The buildings are situated in Dumbarton-road, immediately to the west of the entrance to the Western Infirmary, and adjoining the University Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Botany, Practical Zoology, Practical Physiology, Practical Pharmacy, Operative Surgery, and Public Health Ample provision has also been made for the comfort of students.

Women students are admitted on the same terms as men, and the Carnegie Trust extends its benefactions to students of the College Full particulars may be obtained from Sir W S McCormick, the Carnegie Trust Offices, Merchants' Hall, Edinburgh

Communications relating to the College to be addressed to the Secretary of the Medical Faculty, The Anderson College of Medicine, Glasgow, W 1 Communications relating to the Preliminary Examination in General Education to be addressed to Mr George C Pringle, M A, Educational Institute Office, 47, Moray-place, Edinburgh Communications relating to the Triple Qualification to be addressed to Mr Walter Hurst, Royal Faculty Hall 242, St Vincent-street, Glasgow

The Winter Session will open on Oct 11th

St. Mungo's College and Glasgow Royal Infirmary.—The classes in St Mungo's College qualify for the medical qualifications of the English Scotch, and Irish Conjoint Boards, for the dental diplomas of the English, Irish, and Scottish Boards and under certain conditions, for the various universities, including the University of London Students who have fulfilled the conditions of the Carnegie Trust as regards Scottish birth or extraction, age (16 years), and Preliminary Examination, are eligible for the benefits of this Trust during the whole course of their studies at St Mungo's College The classes are open to male and female students equally The minimum fees for all the lectures, including hospital attendance, necessary for candidates for the Diplomas of the English or Scotch Colleges of Physicians and Surgeons, amount to £120

Further particulars can be obtained from a syllabus which may be procured free on application to the Secretary of the Medical Faculty, 86, Castle-street, Glasgow.

Queen Margaret College (Women's Department of the University)—This is an integral part of the University of Glasgow The classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate The curricula, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. They have access to the University Museum and can borrow books from the University Library, besides having a library *of reference in* Queen Margaret College The School of Medicine is a special feature of the College, and gives full preparation for the medical degrees of the University In July, 1894, for the first time in the history of any Scottish University, women students graduated in medicine in Glasgow University, 682 women have now taken the degree of M B C M or M B, Ch.B of the University of Glasgow and 35 the degree of M.D. The women students attend classes in the various University Buildings at Gilmore-hill and Queen Margaret College the Royal Infirmary the Western Infirmary, and the Victoria Infirmary Facilities for clinical work are given in the Royal, Western and Victoria Infirmaries, in the Maternity, Royal Sick Children's, and other hospitals The Arthur Scholarship is open every third year to students of first year, other Bursaries are open in Arts and Medicine and women are admitted to certain University bursaries and fellowships

The Winter Session will open on Oct 11th.

Royal Infirmary, Glasgow—The ancient connexion between the University of Glasgow and the Royal Infirmary was revived in 1911, when four University Chairs and several University Lectureships were established at the infirmary. New Lectureships in Materia Medica and Pathological Biochemistry have been established this year St Mungo s College, which embraces and continues the original Royal Infirmary *Medical School*, is situated in the infirmary grounds The infirmary has, including the Ophthalmic Department, 700 beds There are special wards for diseases of women, of the throat, nose and ear skin eye burns and septic cases The wards are open to Women Students *At the Outdoor* Department the attendances numbered over 200 000. In addition to the large medical and surgical departments there are departments for special diseases—viz diseases of women, of the throat and nose of the ear, of the eye, of the skin, and of the teeth Five house physicians and 10 house surgeons, who board in the hospital free of charge, are appointed every six months Clerks and dressers are appointed by the physicians and surgeons As a large number of cases of acute diseases and accidents of a varied character are received these appointments are very valuable and desirable There is a modern and fully equipped Electrical Pavilion and year by year the latest and most approved apparatus for diagnosis and treatment has been added Post-graduate Classes are held during August and September in Clinical Medicine Clinical Surgery Clinical Gynæcology Diseases of the Skin, Venereal Disease in the Male, Diseases of the Throat, Nose and Ear and in Diseases of the Eye. Tutorial Classes for senior students are also held in August and September. For information regarding fees and other particulars, application should be made to the Superintendent

Glasgow Western Infirmary.—This hospital adjoins the University of Glasgow. Number of beds 600 Special wards are set apart for Diseases of Women Throat Nose, and Ear, and for Affections of the Skin In the out-patient department there are special clinics for Diseases of Women and for Diseases of the Throat Ear, Teeth, Skin, Venereal Disease, and Electro-Therapeutics The Clinical Courses are given by the physicians and surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom In the Pathological Department the course is both systematic and practical, also post-graduate courses, and extends through the winter and following summer; these are likewise recognised by the University for graduation. Eighteen resident assistants are appointed annually, without salary, from those who have completed their course The fees are as follows.—For Infirmary Attendance: (*a*) For Perpetual Ticket, £12 12*s*; (*b*) for Single Term Ticket £1 11*s* 6*d* For Courses of Instruction: (*a*) Six Months or Two Terms £5 5*s*; (*b*) Three Months or *One* Term, £2 12*s* 6*d* A Clinical Laboratory has been opened, and students receive laboratory instruction from the lecturer on clinical methods Secretary: J. Matheson Johnston, C A., 87, Union-street

A School of Massage, Medical Electricity, and Swedish Remedial Exercises has been established to qualify for the Certificate of the Chartered Society of Massage and Medical Gymnastics.

Royal Hospital for Sick Children, Glasgow.—This institution which was founded in 1882, consists of (1) a hospital at Yorkhill containing 270 cots built on an elevated and central site close to the University and opened in July, 1914; (2) a Dispensary, or Out-patient Department, in West Graham-street, opened in October, 1888; and (3) a country branch at Drumchapel, Dumbartonshire, containing 30 cots, opened *in 1903* Children treated must not be over 13 years *of* age, nor suffer from infectious diseases There are one professorship and two lectureships in the University of Glasgow in connexion with the hospital one professorship and one lectureship on the Medical Diseases of Infancy and Childhood, and one lectureship on Surgery and Orthopædics in Relation to Infancy and Childhood The Professorship is held by Prof Leonard Findlay, the Visiting Physician, and the lectureships are held one by Dr Geoffrey B Fleming, Assistant Visiting Physician, and the other by one *of* the Visiting Surgeons, Mr Alex MacLennan. The lectures are both systematic and clinical but particularly and chiefly the latter In addition special facilities are given for post-graduate study. *Information* with regard to clinical instruction lectures, and post-graduate study may be obtained from the Medical Superintendent

Glasgow Royal Maternity and Women's Hospital, Rottenrow—The new hospital, which was opened in 1908, is in point of size the largest of its kind in Britain and has accommodation for 114 patients A Maternity and Child Welfare Centre has been established in connexion with the hospital, consisting of a complete In-door and Out-door Antenatal Department and an Infant Consultation Clinic In 1925 5147 normal cases and 2589 abnormal cases were treated by the hospital in the In-door and Outdoor Departments Secretary. Mr. William Guy, 146, Buchanan-street Full particulars as to fees and accommodation may be obtained from the House Superintendent at the hospital.

Royal Samaritan Hospital for Women, Glasgow —This hospital, founded in 1886, is the largest purely gynæcological hospital in Great Britain, possessing as it does, 90 beds, which will be increased to 160 when building extensions are completed It offers excellent facilities for clinical instruction in the diseases peculiar to women, treating in the wards and in the out-patient department from 5000 to 6000 cases per annum Lectures and clinical demonstrations are given by members of the surgical staff to students and to post-graduates; and the hospital is represented on the Board of the Glasgow Post-Graduate Medical Association formed for co-ordinating post-graduate medical teaching in all the hospitals University Lectureship associated with the Hospital The Royal Samaritan Lectureship in Gynæcology Lecturer, David Shannon, M B, Ch B., L M, T D For further information application may be made at the Hospital, or to T Mason Macquaker, M A, B L, Secretary, 149, St Vincent-street Glasgow

Glasgow Lock Hospital, 41, Rottenrow, Glasgow This hospital was founded in 1805 for the treatment of females suffering from Venereal Diseases It contains 80 beds There is also a Labour Ward, and a well-equipped Dispensary for out-patient attendances There is now a Lecture Room and Laboratory, equipped with the most modern appliances, for the accommodation of Students who receive their clinical instruction there The number of students attending these classes in 1925 was 183, Post-graduate classes are also held During the course of the past year the hospital has been completely renovated and modernised In 1925 there were 403 in-patients, and 15,318 attendances were made by out-patients at the Dispensary The Secretary and Treasurer is Mr J Neilson Gray, LL B, 65, Bath-street, Glasgow

Glasgow Ophthalmic Institution, 126, West Regent-street, and 131, Wellington-street (30 beds and six cots) —Clinical and systematic course of lectures for students during the winter and summer sessions In-patients, 867, out- or dispensary patients, 15 976, daily average of attendances, 160, total attendances, 48,759 Operations on Wednesdays and Fridays This institution is administered by the Royal Infirmary Secretary and Cashier R Morrison Smith, C A, 135, Buchanan-street, Glasgow

Glasgow Eye Infirmary, Berkeley-street and Charlotte-street —This institution, the largest of its kind in Scotland, was founded in 1824. The average number of new patients for the last ten years has been 26,010 and the total number of cases in 1925 was 67,577 The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine, and by the Royal Colleges of Physicians and Surgeons of England for the Diploma in Ophthalmic Medicine and Surgery. A Venereal Centre has been established, and a Branch Dispensary has been opened in Clydebank. Secretary and Acting Treasurer Harold John Black, 88, West Regent-street, Glasgow The medical session opens in October Post-graduate Classes are being held

Glasgow Ear, Nose, and Throat Hospital, 306, St Vincent-street —15 beds New patients, 7202 Attendances at out-patient department, 23,301 Admitted to in-door department, 480 Clinical instruction is given in Diseases of the Ear, Nose, and Throat Post-Graduate Courses are held during the year Secretary D N. Mackay, 144, St Vincent-street, Glasgow

UNIVERSITY OF ST. ANDREWS (UNITED COLLEGE ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE)

Four Degrees in Medicine and Surgery are conferred by the University of St Andrews—viz, Bachelor of Medicine (M B), Bachelor of Surgery (Ch B), Doctor of Medicine (M D), Master of Surgery (Ch M), a Diploma in Public Health, and Diploma in Dental Surgery (L D S)

The Preliminary Examination is either the Arts or the Pure Science Preliminary Examination The Arts Preliminary includes English Latin or Greek, and Mathematics, and a fourth subject which may be a foreign language or Dynamics In the Science Preliminary Examination French or German may be substituted for Latin or Greek and Mathematics must be on the higher standard Otherwise the subjects are the same as the Arts Preliminary Examination A degree in Arts or in Science in any of the Universities of the United Kingdom and in some colonial and foreign universities shall exempt from the Preliminary Examination On Feb 1st, 1927, new Regulations come into force giving a wider choice in subjects of the Preliminary Examination The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects) Also the Final Examination for a degree in Arts or Science and the Final Examination for the Diploma of L L A

Degrees of Bachelor of Medicine and Bachelor of Surgery—A pre-registration examination is held in Physics and Chemistry Candidates must have been engaged in medical study for at least five years after registering as a medical student In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz, Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants Pathology, Bacteriology, Practical Chemistry, Physics (including the Dynamics of Solids Liquids, and Gases, and the Rudiments of Sound, Heat, Light, and Electricity), Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons and is recognised for the purpose by the University Court Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery, Operative Surgery, Vaccination, Children's Diseases, Fevers, Ophthalmology, Diseases of the Ear, Throat, and Nose, Anæsthetics, Dermatology and Post-mortem Examinations

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect —1 Two of the five years of medical study must be spent in the University of St Andrews 2 The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University

Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court Women are admitted to graduation in Medicine, subject to certain provisions

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery —Each candidate will be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz , first, in Botany, Zoology, Physics, and Chemistry , second, in Anatomy and Physiology , third, in Materia Medica, Pathology and Bacteriology Forensic Medicine and Public Health , and fourth, in Surgery, Clinical and Operative Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and Gynæcology (Systematic and Clinical) The combined fee for tuition and clinical tuition is £182, payable in five annual instalments Additional fees are required for hospital ticket, midwifery cases, laboratory apparatus

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery shall be 33 guineas, and the proportion of this sum to be paid by a candidate at each division of the examination shall be regulated from time to time by the University Court The fee to be paid for the degree of Doctor of Medicine shall be 20 guineas, and for the degree of Master of Surgery 20 guineas The whole medical curriculum can be taken in University College, Dundee, or the first two years in United College, St Andrews For further particulars and details as to scholarships and bursaries application should be made to Prof Charteris, Dean of the Medical Faculty, University College, Dundee

UNIVERSITY COLLEGE, Dundee —This College is one of the constituent colleges of the University of St Andrews In the Conjoint Medical School there are spacious and well-equipped laboratories The complete medical curriculum can be taken in Dundee, beginning in University College (first two years) and continuing in the Conjoint Medical School For classes fees, &c , see under University of St Andrews

ROYAL INFIRMARY, Dundee —The Infirmary contains 461 beds In addition to the ordinary Medical and Surgical Wards, there are special departments for Midwifery (In- and Out-door), for Diseases of Women, of Children, of the Eye, of the Ear, Nose and Throat, and of the Skin , and for Clinical Pathology, Radiology, Electro - therapeusis, and Electro-cardiography An extension providing for a new X Ray Department and Massage Department and for additional Operation Theatre accommodation has been opened recently Clinical teaching is given to male and female Students by the Honorary Staff, post-mortem examinations are conducted by the pathologists All courses of instruction are recognised by the University of St Andrews and the other Boards of the United Kingdom Nine Resident Medical Officers are appointed every six months Clinical clerks and dressers are attached to the Physicians and Surgeons , and Students are appointed as assistants in the pathological department The fees for Hospital attendance are as follows. For Perpetual Ticket, £12, or if paid in instalments, £12 12*s* , Ticket for 12 Months, £4 4*s*. ; Ticket for 3 Months, £1 11*s* 6*d* Further information may be obtained from the Medical Superintendent

---

UNIVERSITY OF ABERDEEN

The University of Aberdeen grants four degrees in Medicine and Surgery—viz , Doctor of Medicine (M D), Master of Surgery (Ch M), Bachelor of Medicine (M B), and Bachelor of Surgery (Ch B) The Degree of Doctor of Philosophy (Ph.D) is also granted in the Faculty of Medicine

Degrees of M B and Ch B —Before commencing his medical studies each student must comply with the following regulations (1) Every Candidate desiring admission to the Faculty of Medicine must be in possession of the necessary " Certificate of Fitness " issued and attested by the Scottish Universities Entrance Board, 81, North-street, St Andrews Forms on which to make application for this Certificate may be obtained from the Secretary to the University of Aberdeen

Candidates, therefore, before entering on the curriculum for the Degree must have passed the Preliminary Examination or hold a qualification recognised as exempting from such examination (3) Have attained the age of 17 years (4) That they have passed the Pre-registration Examination in Physics and Chemistry

Regulations for Pre-registration Courses in Physics and Chemistry have been made by the University in accordance with which the appropriate exemptions can be granted to students

The curriculum for the degrees extends over a period of five years, during which attendance is required in the following subjects Botany, Zoology, Physics, Chemistry (Systematic and Practical), Anatomy (Systematic and Practical), Physiology (Systematic and Practical), Materia Medica and Therapeutics, Practical Pharmacy, Pathology (Systematic and Practical), Medical Jurisprudence, Public Health, Surgery, Medicine, and Midwifery

Candidates must attend for at least three years the medical and surgical practice of a recognised hospital , they must have attended courses of at least nine months in clinical medicine and clinical surgery, and have acted as clerk in the medical and dresser in the surgical wards of a hospital Attendance is required on the practice of a dispensary or the out-practice of a hospital and also on courses in Mental Diseases Fevers, Ophthalmology, Post-mortem Examinations, Venereal Diseases, Tuberculosis, and other special subjects The candidate is also required to have been properly instructed in Vaccination and to have attended at least 20 Midwifery cases

The cost, including Matriculation, Class, Degree, and Hospital Fees, for the whole curriculum leading to the Degrees of M B and Ch B is approximately £240

Besides the Royal Infirmary, students have the opportunity of attending the following institutions : City Fever Hospital, Sick Children's Hospital, General Dispensary, and Lying-in and Vaccine Institutions, Royal Lunatic Asylum, Ophthalmic Institutions, &c

Degrees of M D and Ch M —Candidates for either of these degrees must already hold the degrees of M B and Ch B of Aberdeen A thesis has to be presented and an examination has to be passed in Clinical Medicine (or in some special Department of Medical Science) or Clinical Surgery, as the case may be

Degree of Ph D —For this degree candidates must pursue a course of special study or research during a period of nine academical terms as Research Students in the University of Aberdeen or in any College or Institution that may be affiliated thereto A Thesis must be presented for approval The fee is £10 10*s*

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination.

Application for further information should be addressed to the Secretary of the Medical Faculty

Scholarships and Prizes —In the Faculty of Medicine of the University of Aberdeen there are the following Bursaries, Scholarships, and Prizes —Bursaries about 15 Bursaries (competition and presentation) are open each year, of £15 to £30 per annum in value, most of them being tenable for three years Scholarships · five Post-Graduate Scholarships, value £36 to £160 per annum Prizes and Medals 15 Gold Medals and Prizes for proficiency in special departments, &c

Clinical Instruction is given in the Aberdeen Royal Infirmary (270 beds) by the physicians and surgeons on the staff

ABERDEEN ROYAL MENTAL HOSPITAL.—Contains, with hospital attached to main institution and agricultural branch about 950 beds Clinical instruction is given to students during three months in summer. Clerk and Treasurer, Mr. A. Scott Finnie, 343, Union-street, Aberdeen

SCOTTISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

SCOTTISH CONJOINT BOARD

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or Glasgow, or both, the student may obtain the diplomas of the three Bodies

The three Bodies grant their Single Licences only to candidates who already possess legal qualifications in Medicine or Surgery Copies of the Regulations for the Single Licence of any of the Bodies may be had on application to the respective secretaries

Professional Education —The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of instruction Physics, three months, Elementary Biology, three months; Chemistry, six months; Practical or Analytical Chemistry, three months, Anatomy, during at least six months, Practical Anatomy, twelve months, Physiology, six months; Practical Physiology, three months, Materia Medica, three months, Pathology (including Practical Pathology), nine months, Practice of Medicine, six months; Clinical Medicine, nine months, Principles and Practice of Surgery, six months; Clinical Surgery, nine months; Midwifery, three months, Gynæcology, one course of not less than 13 meetings, Diseases of Children, one course of not less than 13 meetings, Medical Jurisprudence and Public Health, three months The certified attendance on lectures, demonstrations, and practical work must not be less than three-fourths of the total number of roll-calls Every student undergoes a course of Practical Midwifery, but before attending at labours he is required to attend a course of lectures on Surgery and Midwifery and to hold the offices of Clinical Medical Clerk and Surgical Dresser. He must also attend for two and a half months instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of Practical Pharmacy.

The student must attend for 27 months the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction and possessing distinct staffs of physicians and of surgeons He must act as Surgical Dresser and Medical Clinical Clerk for not less than six months in the wards in each case, and receive practical instruction in administration of anæsthetics He must attend for six months the practice of a public dispensary especially recognised by any of the above authorities, or the out-patient practice of a recognised general hospital This attendance should be made after the student has passed the First and Second examinations

Candidates are also required to attend the following courses Diseases and Injuries of the Eye, three months, Insanity, three months; Infectious Diseases, three months. Gynæcology, three months, Diseases of Children, three months

The curriculum lasts for five years, the fifth year being devoted to clinical work

There are four professional examinations:—

First Examination includes Physics, Chemistry, and Elementary Biology.

Second Examination includes Anatomy and Physiology and Histology; and candidates may be admitted to this examination at the end of the second year of medical study.

Third Examination includes Pathology and Materia Medica with Pharmacology

Final Examination —The Final Examination shall not be taken earlier than the end of the fifth year of study and shall embrace the following subjects — Medicine, including Therapeutics, Medical Anatomy, and Clinical Medicine, Surgery, including Surgical Anatomy, Clinical Surgery, and Diseases and Injuries of the Eye, Midwifery and Diseases of Women, and, if not passed previously, Medical Jurisprudence and Public Health, but it is optional to candidates who have passed the Third Examination to be admitted to the subject of Medical Jurisprudence and Public Health on lodging certificates of having attended the necessary course in that subject at any time, but the subjects of Medicine, Surgery, and Midwifery shall be taken together at any time after the end of the fifth Winter Session, provided that a period of 24 months has elapsed since passing the Second Examination All candidates shall be subjected, in addition to the written and oral examinations, to clinical examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface Markings, &c The fees payable for the Final Examination shall be—for the whole examination, £15, for re-entry after rejection, £5, and for the subjects of Medical Jurisprudence and Public Health when taken separately, £5, with £3 for re-entry in that subject

There are four periods of examination annually During the ensuing period thrice in Edinburgh and once in Glasgow, in 1926–27 The Registrar in Edinburgh is Mr D L Eadie, 49, Lauriston-place, and the Registrar in Glasgow, Mr Walter Hurst, 242, St Vincent-street, to whom fees and certificates must be sent for the respective examinations, and from whom particulars of fees can be obtained

For students registered with the General Medical Council after Jan 1st, 1923, more extensive Regulations are in force, and candidates applying for Regulations should state date of registration.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH THE MEMBERSHIP AND FELLOWSHIP

In addition to the diplomas granted by the Scottish Conjoint Board the Royal College of Physicians grants its Single Licence to candidates already possessing legal qualifications for professional practice

The Royal College of Physicians of Edinburgh grants a *Membership* and a *Fellowship*

Membership —A candidate, who must be a Licentiate of a British or Irish College of Physicians, or a graduate in medicine of a University, approved by the Council, and 24 years of age, is examined in medicine, therapeutics, and in any branch of the departments of medicine specially professed, such as general pathology, psychology, public health obstetrics, gynæcology, diseases of children, tropical medicine, or medical jurisprudence The fee for the Membership is £36 15*s*, 15 *guineas* of which will be returned to any successful candidate who was already a Licentiate of the College at the time of qualifying for the Membership.

Fellowship —The Fellows are selected from the ranks of the *Members* The fee is £64 18*s*

ROYAL COLLEGE OF SURGEONS OF EDINBURGH: THE FELLOWSHIP.

The Royal College of Surgeons of Edinburgh also admits to the examination for its Single Licence any candidates who hold a Diploma in Medicine of any British, Indian, or Foreign university or of any British College of Physicians, or of the Society of

Apothecaries of London or Apothecaries' Hall Dublin, granted under the provisions of the Medical Act, 1886, whose preliminary examination and course of professional study is proved to be sufficient to fulfil the requirements of the College, or to those who have passed a full examination for any of the above. Female practitioners are admitted to the Licence of the College and also to the Fellowship, and the regulations apply to practitioners of either sex.

The Royal College of Surgeons of Edinburgh grants a diploma of Fellowship after examination to the holders of the surgical degrees or diplomas of such British examining bodies, as well as of the holders of such surgical degrees of the Universities of Canada, Australia, New Zealand, and the Indian Empire as are recognised by the College.

The Fellowship.—Candidates for the examination must be 25 years of age and must have been engaged in practice for at least two years. The examination is of a practical nature, partly written and partly viva voce, and must include surgery and surgical anatomy, operative surgery, and clinical practice. One optional subject must also be taken, the range of these specialisms covering nearly every branch of medicine. Candidates are not allowed to appear for more than three times at the examinations. The fee to be paid on entering for examination for Fellowship is £45, £10 of which is remitted to those who already hold the Licentiateship of the College. Candidates rejected at the examination obtain repayment of fee less £10 retained for examination expenses. One month's notice of intention to appear for examination must be given by the candidate to Mr. D. L. Eadie, 49, Lauriston-place, Edinburgh, clerk to the College, together with credentials signed by two Fellows of the College, one of whom must be a resident in Edinburgh, otherwise a special application with six testimonials must be made to the President and the Council of the College.

THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Like the preceding corporations, the Royal Faculty of Physicians and Surgeons of Glasgow grants a Fellowship and a Licence to be held separately.

Fellowship.—The Fellowship of the Faculty is granted after examination in medicine or surgery, together with an optional subject, which may be anatomy or physiology or be selected from any special branch of medicine or surgery. Fourteen days' notice must be given by the candidate of his intention to present himself to Mr. Walter Hurst, the Faculty Hall, 242, St. Vincent-street, Glasgow. The fee for the Fellowship is £50, £10 of which sum is returned to any successful candidate who already holds the Licence of the Faculty. In certain circumstances Fellows may be elected as a mark of distinction.

Licence.—The Licence of the Royal Faculty is granted as a separate qualification to qualified practitioners in Medicine after examination in surgery, including surgical anatomy and clinical surgery. The fee is 15 guineas.

SCOTTISH PROVINCIAL ANCILLARY SCHOOLS AND HOSPITALS

The hospitals which are recognised by the Scottish Conjoint Board as places where professional study for their diplomas can be pursued are all those institutions which feed the medical faculties of the universities. In addition the Scottish Boards recognise all the places which are recognised by the English Conjoint Board (see p. 434) and the Irish Conjoint Board (see p. 455).

III.—IRELAND

THE UNIVERSITIES

UNIVERSITY OF DUBLIN, TRINITY COLLEGE (SCHOOL OF PHYSIC)

Matriculation.—In order to join the School of Physic students pass a matriculation examination. University students take the Entrance of Trinity College and a Junior Freshman Term or a special Medical Preliminary. Extern Students, any examination recognised by the General Medical Council. The winter courses begin on Oct. 1st.

Pre-registration Examination in Elementary Physics and Chemistry.—Before beginning the five years' Medical curriculum students must pass an examination in elementary Physics and Chemistry. This examination is held at the end of September, in January, in March, and in June. Courses in preparation for it may be taken in the School of Physic. On passing this examination Medical students should register as such with the General Medical Council.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of registration. The Arts course may be taken concurrently with the Medical course, and the B.A. degree need not be taken before the final medical examinations but the Medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Lectures—Botany, Zoology, Physics and Practical Physics; Systematic, Descriptive and Applied Anatomy; Chemistry and Practical Chemistry; Histology, Physiology, Practical and Applied Physiology; Practice of Medicine; Midwifery and Gynæcology, Pathology and Bacteriology; Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Surgery and Operative Surgery; (2) three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Hospital; (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months; (5) Practical Midwifery with Clinical Lectures, including not less than 20 personally conducted cases, six months; (6) Ophthalmic Surgery, three months. Three groups of examinations have to be passed: Preliminary Scientific Examination, including Physics and Chemistry, Botany, and Zoology. The Intermediate Medical, Part I., including Anatomy, Physiology, and Organic Chemistry; and Part II., including Applied Anatomy and Applied Physiology; and the Final Examination, which is divided into Part I., Materia Medica and Therapeutics, Hygiene and Jurisprudence, Pathology and Bacteriology; and Part II., Medicine, including Clinical Medicine and Mental Diseases; Surgery, including Operative and Ophthalmic Surgery; Midwifery and Gynæcology. Part I. may be passed in the fourth year and Part II. completed at the end of the fifth.

Doctor in Medicine.—A Doctor in Medicine must have passed all the qualifying examinations and must be a B.A. of three years standing. He must also submit a thesis and pass an Examination before the Regius Professor of Physic.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study, or study and practice, of his profession. He must then pass a special examination.

Master in Obstetric Science.—A Master in Obstetric Science must be a Bachelor in Obstetric Science of two years' standing and must produce evidence of having been engaged in the study of Obstetric Medicine and Surgery during two years He is then required to pass a special examination

Diploma in Gynæcology and Obstetrics—A post-graduate diploma is conferred upon registered medical practitioners who take a six months' course at the Rotunda Hospital or other recognised institution, a six months' course in Trinity College, and then pass a special examination The minimum time required for the complete course is nine months

Bachelor in Dental Science and Master in Dental Science—The regulations under which these degrees are awarded can be obtained by application to the Registrar of the School of Physic

All Degrees and Courses of Instruction are open to women students

Post-graduate Instruction—Arrangements have been made, with the approval of the Board of Trinity College, for a post-graduate course of instruction at the School of Physic during the autumn from Monday, Sept 13th, to Saturday, Oct 2nd Members of the class can reside in college rooms and dine on commons

Clinical Instruction—The hospital facilities for clinical instruction available in Dublin will be described below

NATIONAL UNIVERSITY OF IRELAND

Matriculation—All students intending to proceed to the medical degree of the University of Ireland must pass a matriculation examination, the examination taking place in June and September in Dublin and at certain local centres All students must pass in five subjects (three of which must be Irish, English, and mathematics) All students must pass in Irish except students not born in Ireland, and other students whose home residence shall have been outside Ireland during the three years immediately preceding their matriculation, but all such students will be expected to attend a course of instruction in Irish Literature and History prior to obtaining any degree in the University The following are the subjects for examination —1 Irish 2 Latin or Greek 3 French, German, Italian, Spanish, Portuguese, Welsh, or any other modern language approved by the Senate 4 English 5 Mathematics 6 Latin, Greek, French, German, Welsh, Spanish, Italian, Portuguese, or any other modern language approved by the Senate, History, Geography, Applied Mathematics, or Physics as an alternative, Chemistry, Botany, and for women candidates only, Physiology and Hygiene. Students entering for degrees in Medicine or Dentistry, if already registered by the General Medical Council, must take Irish, Latin, English, Mathematics, and a fifth subject

The medical degrees granted are —

M B, B Ch., and B A.O, and M D, M.Ch, and M A O, Ph.D—Printed forms of application for admission to any medical examination may be had from "The Registrar, The National University of Ireland, Dublin"

The Constituent Colleges of the National University of Ireland at which the full curriculum for medical degrees can be obtained are University College, Dublin; University College, Cork; and University College, Galway.

UNIVERSITY COLLEGE, DUBLIN *—The University and the College were created by the Irish University Act, 1908, and by Charters issued in December, 1908 Former students of the Cecilia-street School of Medicine who graduated in the Royal University may become graduate members of the new College The constitution of the College, like that of the Constituent Colleges of Cork and Galway, provides for a governing body, an academic council consisting of professors and coöpted lecturers, a body of graduate members, and a body of student members matriculated in the University The first professors were appointed by the Dublin Commissioners Irish Universities Act, 1908

Matriculation—Almost all the students of the College are matriculated students of the National University of Ireland.

Universities Examinations in Medicine—The First Examination includes Applied Physics, Applied Chemistry, Botany, Zoology, and Applied Biology The examination may be taken in two parts Part I, Physics and Chemistry, Part II, Botany and Zoology Honours may be obtained only when both parts are taken as one examination The Second Examination includes Anatomy and Physiology Both must be passed at the same time The Third Examination includes Pathology, Medical Jurisprudence and Hygiene, and Materia Medica

Degrees of M B, B Ch, and B A O—The Examination in Medicine, Midwifery, Surgery, and Ophthalmology includes both the theoretical and the clinical branches No student can enter for the M B., B Ch, or B A O until the end of the fifth year when the curriculum has been completed The degree of M D may be obtained either by examination or on published work

Fees—The fees for Courses may be obtained on application to the Registrar for the College publications Information concerning these, and the scholarships and exhibitions of the College can be obtained from the Dean of the Faculty, Prof E P McLoughlin

UNIVERSITY COLLEGE, CORK THE SCHOOL OF MEDICINE —The building is provided with a very large, well-ventilated dissecting room supplied with electric light, with physiological, toxicological, pathological and pharmaceutical laboratories, materia medica, anatomical and pathological museums, as well as a collection of surgical and obstetrical instruments and appliances There are well-appointed physical, chemical, and biological laboratories, a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden The plant houses are well filled with plants and are open to the students in the class of Botany The Library contains about 70,000 volumes and is open daily during term time to students The Medical Museum occupies a large room erected at the northern end of the medical buildings There are Students' Clubs for men and women students of the College and various athletic clubs, the last of these holding a public meeting yearly in the Mardyke grounds

All students who have been admitted as matriculated students are required to attend before the President and sign the Roll of Matriculated Students Students who are candidates for degrees in the National University of Ireland must have passed the Matriculation Examination of that University or other recognised examination, and medical students must have passed a preliminary examination recognised by the General Medical Council For information as to the conditions and courses of the Matriculation Examination application may be made to the Registrar, National University, Dublin

Admission of Medical Students—Students in the Faculty of Medicine who have passed the First Professional Examination of the Conjoint Examinations of the Royal College of Physicians and the Royal College of Surgeons in Ireland, or of the Royal College of Physicians and Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, or of the Royal College of Physicians, London, and Royal College of Surgeons, England, may be admitted to the rank of second-year students on making application to the Council and submitting a certificate of having passed the examination Similarly, students who have passed the Second Professional Examination of the same Colleges may be admitted to the rank of third-year students; and those who have passed the Third Professional Examination of the Dublin Colleges, or of the Edinburgh Colleges and Glasgow Faculties, may rank as fourth-year

---

* No returns

Residence of Students —There is no accommodation for the residence of students within the College, but students not living at home, or with relatives or friends, sanctioned by their parents or guardians, are required to live in a hostel or in recognised lodgings, a list of which can be obtained from the Secretary All students are required to register their addresses each session in the book kept for that purpose in the hall porter's office, and to notify immediately to the Registrar any change of address during the session The Honan Hostel, adjoining the College, is equipped by private endowment A number of sets of rooms, together with recreation and common rooms, are provided for lay students who may desire to live there For full particulars apply to the Warden The Ursuline Convent, Blackrock, has a house of residence, quite separate from their Secondary School, for Catholic women students

Clinical Instruction —Students may attend the South Infirmary, Cork North Charitable Infirmary, the Mercy Hospital, the Cork District Lunatic Asylum, the Victoria Hospital for Diseases of Women and Children, the County Lying-in Hospital, the Cork Maternity, Fever, the District, and Ear, Eye, and Throat Hospitals

Complete information with regard to class fees, scholarships, and prizes can be obtained from the Dean of the Medical Faculty, Professor A E Moore

*South Charitable Infirmary and County of Cork General Hospital** (100 beds) —Clinical instruction is given daily in the wards Special instruction on Diseases of Women and Children will be given in the special wards for such cases Fee for nine months, £12 12*s* ; for six months, £8 8*s* , for three months, £4 4*s* Two resident pupils will be appointed by competitive examination

Cork North Charitable Infirmary and County and City of Cork General Hospital (121 beds) —Clinical instruction is given daily in the wards by the physicians and surgeons to Senior students four days weekly and to Junior students on two days weekly Medical and Surgical classes are also held daily in the extern department Fee for 12 or nine months £12 12*s* , for six months £8 8*s* , and for three months, £4 4*s* Three resident students are appointed quarterly by the medical staff All resident students are required to be registered students of the hospital There is a special department for treatment of diseases of the eye, ear, throat, and nose, and a special dental department The hospital contains a fully equipped Pathological Department and a large and extensive X Ray Department has recently been added

Mercy Hospital —Clinical hospital recognised by the General Nursing Council for Ireland This hospital contains 130 beds for medical and surgical cases There is also a daily extern for medical and surgical cases, as well as for diseases of the eye, ear, and throat Extern medical and surgical, also eye, ear, and throat attendances for 1925 23 800 ; intern patients, 1770 Daily average, 97 4 Two resident students Honorary Secretary to the Staff W. Rahilly Special apartments for nurses and nuns under training

Cork Mental Hospital (Psychological Medicine) —A course of Clinical Lectures on Mental Diseases and Allied Neuroses will be delivered by the Resident Medical Superintendent in the Cork Mental Hospital as soon as possible after the opening of the Trinity Term The lectures will comprise Normal Psychology , Psychology of the Insane; Psychoses, Statistics, Classification, Ætiology, Symptomatology, Diagnosis, Prognosis, Pathology and Treatment , Psychoneuroses , Neuroses ; Psycho-Analysis The course will be illustrated by typical cases Special Post-Graduate facilities are afforded to candidates who desire to obtain a diploma in Psychological Medicine For further particulars apply to Dr Owen F McCarthy, Resident Medical Superintendent

Victoria Hospital (Incorporated) (Cork) —There are 75 beds Clinical instruction on Diseases Peculiar to Children is given The extern department is open daily at 9 30

County and City of Cork Lying-in Hospital (Ennville, Western-road; founded 1798) —This hospital contains 22 beds an Extern Midwifery Department, Gynæcological Department, Extern Department for Women, and Child Welfare Centre Training Centre for Midwives, preparing for C M B examinations Fee for six months' attendance, including clinical lectures, £5 5*s* For further particulars apply to Lucy E Smith, M D , secretary to staff.

Cork Maternity (Batchelor's Quay) —Three resident pupils are taken into the Maternity Poor women are attended at their own homes and there are 8 intern beds A Child Welfare Centre and Clinic was established in 1919 Clinical lectures are delivered during the session There is an extern department for the treatment of women's and children's diseases Fee for attendance at clinical lectures and certificate £5 5*s* Honorary secretary to staff (*vacant*)

Cork Fever Hospital —Upwards of 500 cases of various forms of fever and zymotic disease are treated yearly in this hospital The Resident Medical Officer gives instruction in Practical Pharmacy, a certificate of which is necessary for the National University and Colleges of Physicians and Surgeons of Edinburgh

Cork District Hospital (Douglas-road , 1200 beds) This hospital includes special buildings for fever and other infectious diseases (100 beds) , for children's diseases (100 beds) , and a Lock hospital, the only one in the South of Ireland (80 beds) It affords an extensive field for the study of all classes of diseases, acute and chronic, including special departments for gynæcology and diseases of the skin and nervous system The physicians and surgeons visit the hospitals every morning at 10 o'clock Lectures and clinical instruction are given daily in the wards by the physicians and surgeons Further particulars may be obtained from Dr D Morrissy, 88, South Mall, Cork, honorary secretary, medical staff Post-Graduate classes for the M D &c are held, also classes for D P H and kindred examinations

Cork Eye, Ear, and Throat Hospital (Western-road) This hospital is open to students attending the University College and others Certificates of attendance for three or six months can be obtained The hospital contains 35 beds Over 3000 cases are treated during the year A course of lectures is delivered during the session , also a post-graduate course of instruction For further information apply to Dr Arthur Sandford, Eye, Ear and Throat Hospital

UNIVERSITY COLLEGE GALWAY: SCHOOL OF MEDICINE —The College contains a well-lighted and ventilated dissecting room and an anatomical lecture theatre; physiological, pathological, pharmaceutical, chemical, and physical laboratories; anatomical, pathological, gynæcological, and materia medica museums, as well as large natural history and geological museums and an extensive library in which students can read and from which they can borrow books There are 12 Entrance Scholarships, value £20 each, for which Medical Students compete with other students on the Entrance Course. In the Second, Third, and Fourth years three Scholarships in each year, value £20 each, are reserved for Medical Students H H Stewart Scholarships (£10 a year for three years) are awarded by the University in Anatomy and Physiology at Second Medical Examination amongst

---

QUEEN'S UNIVERSITY OF BELFAST.

There are six degrees in the Faculty of Medicine of the University—viz, Bachelor of Medicine (M B), Bachelor of Surgery (B Ch), *Bachelor of Obstetrics* (B A O), Doctor of Medicine (M D), Master of Surgery (M Ch), and Master of Obstetrics (M.A O) The University also grants a Diploma in Public Health, particulars of which will be found in the University Calendar The degrees of M B, B Ch, and B.A O. are the primary degrees in the Faculty of Medicine, and are conferred at the same time and after the same course of study No student is admitted to the final examination for these degrees until he has shown. (1) that he is a matriculated student of the University, (2) that he has completed the prescribed course of study in the Faculty of Medicine extending over a period of not less than five academic years from the date of his registration as a student of Medicine by the General Council of Medical Education and Registration of the United Kingdom, (3) that he has passed the several examinations prescribed, (4) that he has attended in the University during three academic years at least the courses of study prescribed for such degrees (the Senate may accept, for not more than two academic years of the required five, courses of study pursued in any other University or School of Medicine approved by the Senate); and (5) that he has attained the age of 21 years Every candidate for admission as a matriculated student of the University shall pass such Matriculation Examination or fulfil such other test of fitness as may be prescribed by the Senate, which may prescribe the conditions under which students who have passed the Matriculation or Entrance Examination of any other University or College approved for that purpose (or who have fulfilled such other test of fitness as may be prescribed) may be exempted from passing the Matriculation Examination of the University. For information as to Scholarships and Prizes inquiry should be made of the Secretary of the University

Primary Degrees of M B, B Ch, B A O—All candidates for these degrees must satisfy the examiners in the subjects of four examinations

The First Medical Examination—The subjects of this examination are Chemistry (Inorganic and Organic), Experimental Physics, Botany and Zoology. The examination will be divided into two parts which may be taken separately I, Chemistry and Physics, II, Botany and Zoology

The Second Medical Examination—The subjects are Anatomy and Practical Anatomy, Physiology and Practical Physiology Candidates who have previously passed the First Medical Examination may present themselves for this examination at the close of their second year.

The Third Medical Examination—The subjects are (1) Pathology and Practical Pathology, (2) Materia Medica, Pharmacology and Therapeutics; (3) Medical Jurisprudence; (4) Hygiene Candidates who have previously passed the Second Medical Examination may present themselves for this examination at the close of the third year Attendance on a course in any subject of the Third Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the Second Medical Examination

The Fourth Medical Examination—The subjects are (1) Medicine, (2) Surgery, (3) Midwifery, (4) Ophthalmology and Otology This examination may be taken in two parts I, Systematic, II, Clinical, Practical and Oral. Candidates who have previously passed the Third Examination may present themselves for Part I of the Fourth Examination at the close of the fourth year, provided that they have fulfilled the necessary requirements as to attendance, &c, on the courses of instruction in the subjects of examination Candidates who have passed Part I of this examination may present themselves for Part II at the close of the fifth year, provided that they have fulfilled the necessary requirements as to hospital attendance on the various clinical courses in the subjects of examination Parts I and II may be taken together at the close of the fifth year Attendance on a course in any subject of the Fourth Medical Examination shall not entitle a student to a certificate of attendance unless he has passed in the subjects of the Second Medical Examination

Degrees of M D, M Ch, and M A O—These degrees are not conferred until the expiration of at least three academic years, or in the case of graduates of the University in Arts or Science of at least two academic years, after admission to the primary degrees in the Faculty of Medicine Every candidate must show that in the interval he has pursued such courses of study, or been engaged in such practical work as may be prescribed These degrees may be conferred by the Senate either (*a*) after an examination, which includes written, oral, clinical, and practical examinations, or (*b*) on the submission of a thesis or other evidence of original study or research, to be approved by the Faculty of Medicine after an oral or other examination of the candidate on the subject

The Medical School—The Donald Currie Chemical Buildings contain a lecture theatre, a preparation room, a chemical museum, a large class-room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes and balance room, provided with all modern appliances The Anatomical Department contains a large and well-lighted dissecting-room a lecture-room, a professor's and demonstrator's room, a bone-room, and a laboratory for microscopic and photographic work The Medical Museum is in the same building The Jaffé Laboratories for Physiology comprise a lecture theatre, laboratories for practical work in chemical physiology, histology, and experimental physiology, and in addition small private research rooms, including balance, galvanometer, and centrifuge rooms The Musgrave Pathological Laboratory —In this department opportunity is afforded for research in pathology and bacteriology The department is in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases A course in pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, the diagnosis of cases of infectious diseases, &c The certificate issued to members of the class in bacteriology qualifies for the D P.H degree The Pharmaceutical Laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines

Clinical Instruction —The following institutions are recognised by the University as affording proper opportunities for clinical instruction. the Royal Victoria Hospital, the Mater Infirmorum Hospital, the Union Hospitals, the Belfast Hospital for Sick Children, the Belfast Maternity the Ulster Hospital for Women and Children, the Ulster Eye, Ear, and Throat Hospital, the Belfast Ophthalmic Hospital, the Purdysburn Fever Hospital, and the Belfast District Lunatic Asylum

Royal Victoria Hospital, Belfast (436 beds) — Students eligible for McGrath, McQuitty, Malcolm, Coulter Smyth and Elwood Scholarships aggregate annual value £185 Twelve House Surgeons and House Physicians Thirty-six resident pupilships, three months each, annually for Senior Students, of which a proportion is allotted to Women Students, Special Departments for Radiology, Clinical Pathology V D, Dermatology, Gynæcology, Vaccine Therapy, Electrocardiography, Dentistry

MATER INFIRMORUM HOSPITAL, BELFAST —This hospital contains 270 beds and is open at all hours for the reception of accidents and urgent cases Clinical instruction is given daily by Physicians and Surgeons Surgical operations are performed daily The outpatient departments in Medicine and Surgery, also the special dispensaries for Gynæcology, Ear, Eye and Throat, Electrotherapeutics, Venereal Diseases are very largely attended and afford valuable opportunities to students for the study of those subjects A House Physician and two House Surgeons are elected every six months Resident pupils are admitted as the vacancies arise Three Exhibitions and a Gold Medal are competed for annually in June Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom

* No returns

MERCER'S HOSPITAL.—This hospital, founded in 1734, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and within five minutes' walk of Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork-street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the posts of Resident Pupil, &c. There is a large dispensary for out-patients and a modern X ray department. An electro-cardiograph has been installed. Students of the hospital are permitted to attend the gynæcological department, where they receive practical instruction. There are special wards for the treatment and study of children's diseases. A gold medal is awarded annually to the best student. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements.

Appointments.—A House Surgeon is appointed annually. There are six men and two women Resident Pupils, and Clinical Clerks and Dressers are appointed from amongst deserving members of the class.

Fees.—Winter, six months, £8 8*s*.; Summer, three months, £5 5*s*.; nine months, £12 12*s*.

For further particulars apply to Dr. Bethel Solomons, Hon. Sec., Medical Board, 42, Fitzwilliam-square.

NATIONAL MATERNITY HOSPITAL, Holles-street, Dublin.—Established 1894. The hospital consists of Intern and Extern Maternity, Gynæcological Wards, and a Dispensary for the treatment of Diseases of Women and Children. During the year 1925–26, 1302 cases were admitted, 846 confinements took place in the hospital, and 342 gynæcological operations were performed. In the district 653 confinements took place. 6113 patients attended the dispensary for treatment. Every facility is given for the carrying out of practical work. Undergraduate and Post-graduate courses are arranged at any time. Certificates of attendance at this hospital are recognised by all the licensing bodies. Terms: Undergraduate courses, 8 guineas for certified course (6 months), 3 guineas per month for uncertified course; Post-graduate courses, 3 guineas per month, 1 guinea for each extra week. Clinical Lectures are given daily and Oral Lectures four times per week. The L.M. Diploma is given by special examination which is held three times a year. Entrance fee 1 guinea, certificate 4 guineas. During the past year 98 graduates availed themselves of the Post-graduate courses. Further particulars can be obtained from the Master, Dr. P. T. McArdle, 27, Merrion-square; or from the Secretary, Holles-street, Dublin.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS (HOUSE OF INDUSTRY HOSPITALS), Dublin.*—These hospitals contain 330 beds—130 for Surgical cases, 80 for Medical cases, 78 for Fever and other Epidemic Diseases, and an Auxiliary Wing of 42 beds. A Resident Physician and a Resident Surgeon are appointed each half year and are paid for their services. 20 Resident Clinical Clerks are appointed each quarter and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced students but also to those who are qualified in Medicine and Surgery. The Dressers are selected from among the best qualified of the pupils without the payment of any additional fee. Women students are eligible for election as residents and special apartments are reserved for their use. For prospectuses apply to Mr. Adams McConnell, F.R.C.S.I., Hon. Secretary, 69, Fitzwilliam-square, Dublin.

ROTUNDA HOSPITAL, Dublin.—This institution is the largest combined gynæcological and maternity hospital in the British Empire. Over 4000 confinements are attended annually and 500 gynæcological patients admitted. Students can take out their necessary gynæcological and midwifery practical courses. The work of the hospital is carried on continuously through the year and consists of daily clinical instruction in the maternity department and examination and operations in the gynæcological department. Qualified students are given facilities for studying and assisting in the management of all abnormal cases so far as is practical. An antenatal dispensary is largely conducted by the senior qualified students of the hospital under the supervision of the staff. A special class in gynæcological examination and diagnosis is conducted by the Assistants to the Master. The appointments on the staff of the hospital are given to qualified past students of the hospital who have taken the L.M. and consist of Extern Assistants for six months, one being appointed every three months. From these the Assistants to the Master are appointed. Women students can reside in the hospital on the same terms as men. The L.M. is granted by examination after a six months' course. Fees for Intern students: one month £6 6*s*., months other than the first £4 4*s*., three months £12 12*s*., six months £21. Special gynæcological class £2 2*s*. per month. For further particulars apply to the Master, Dr. Gibbon FitzGibbon.

ROYAL CITY OF DUBLIN HOSPITAL.—Founded 1832, enlarged 1851, rebuilt 1893. 135 beds. There is a special wing for the treatment of fevers and contagious diseases founded by the late Mr. Drummond. Secretary: W. H. Leadbeater. There is a large nursery where special opportunities are afforded for the study of diseases of children, both medical and surgical. There are also special wards for ophthalmic, aural, and gynæcological cases. There is a largely attended out-patient department where students are allowed to attend accidents and dress cases under supervision. Six resident pupils are appointed every three months. A House Surgeon and a House Physician are appointed annually.

ROYAL VICTORIA EYE AND EAR HOSPITAL, Dublin.*—Established 1844. Incorporated 1897. 102 beds. In-patients, 1499; out-patients, 8492.

DR. STEEVENS' HOSPITAL, Dublin (*Kingsbridge*).—Established 1720. 250 beds, only 150 now in use. Patients, intern, 1197; extern patients 7313; extern dispensary attendances, including special V.D. Clinic, 44,529. There is accommodation for 10 resident pupils, each of whom is provided with a separate bedroom, and board is supplied by the hospital at a reasonable rate. There is an Electric Massage Department and a "Sun-Ray" Department. All information with regard to the terms for such residency can be had from the Resident Surgeon at the Hospital. Secretary: E. D. F. Banks.

ST. VINCENT'S HOSPITAL AND DISPENSARY, Dublin.—Established 1834. 200 beds. Clinical Lectures in Medicine and Surgery are held from October to June. Special classes for Juniors from October to December. Pathological and Bacteriological Demonstrations are given every Thursday, and instructions in the use of Laryngoscope and Otoscope for Senior students every Saturday. Medals and Prizes: the Bellingham gold medal in Medicine and the O'Farrell gold medal in Surgery are offered for competition at the end of the summer session, as well as junior prizes, also the Surgeon McArdle Prize, value £20. In the last term there was opened a new External Department and a new Pathological Laboratory. Dr. Meenan, Hon. Secretary, 28, Fitzwilliam-square.

WE take this opportunity of thanking the officials of Government Departments and the Deans and Secretaries of the various institutions for their kind cooperation in enabling us to bring the information contained in our Students' Number up to date.

figures (see p 480) indicates that the various ctors which led to the multiplication of students ave lost their force. and there is no reason to think at the medical profession will be overcrowded in he immediate future Further, we do not know that the unusual addition to the roll of qualified men, corresponding with the swelling of the students' ranks has brought any undue consequences with it, even with the increased number of doctors that we now have the medical profession is not to-day redundant, for the amount of work that has to be done steadily swells, as does the number of varying avenues which have to be traversed by the followers of medicine This is the fact which should be remembered when we are told dogmatically that examinations must be stiffened to keep out the weaker candidates Things are not as simple at the threshhold of a learned profession as they are at the doors of a test match On these occasions unusual barriers can be erected and stringent measures taken to regulate ingress when too many persons are expected And the precautions have a logical effect Access to entertainments is strictly guarded in defence of those who have paid their money—translated into terms of examinations, for those who have learned their work But examinations especially in such a far-ranging collection of subjects as medicine, do not play the same practical rôle A serious proportion of those who have paid with their industry and intelligence for the opportunity to enter the qualified ranks do not succeed assuredly or promptly, and it is this high element of uncertainty which conduces to the failure of nervous students No general relaxation of standard is desired from the authorities while, from the economic aspect a stiffening can be justified on public grounds by the satisfactory number of candidates but the ideal part which the examinations should play in the curriculum has not yet been found, despite repeated and real research And the uncertainty of the results of these tests does affect some examinees seriously.

We can welcome our recruits with the assurance that there is plenty of work for them to do, and we can congratulate them because that work has to be done in every section of professional endeavour in fairer and more generous circumstances than used to prevail in times not far away With regard to contract practice, hope lies in that betterment of organisation which experience is bringing, and which has been in the minds of many since the passage of the National Insurance Acts, the position does not promise to improve pecuniarily, and consolation must be sought in the reflection that, as such practice stands at present, it is hugely better in its material results than it was 20 years ago when it was admittedly scandalous The Services only in the last few weeks, have made drastic revision of their regulations in favour of their medical staffs, and the authorities at medical schools will certainly have noted the opportunities now offered to their pupils Elsewhere salaries have risen, and medical officers though poorly paid in comparison with those who discharge other public duties receive better terms, and their terms have not been wholly dictated by the general rise in prices, but have followed on a wider appreciation by the public of the meaning and value of preventive treatment and organised therapeutics These are solid reasons for congratulating our students upon their choice of a career If entrance to the arena is fenced around with difficulties there is zest in the surmounting of these And the return for success is not the pleasure of looking on, but the privilege of playing

Mercer's Hospital —This hospital, founded in 1734, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and within five minutes' walk of Trinity College It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork-street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the posts of Resident Pupil, &c There is a large dispensary for out-patients and a modern X ray department An electro-cardiograph has been installed Students of the hospital are permitted to attend the gynæcological department, where they receive practical instruction There are special wards for the treatment and study of children's diseases A gold medal is awarded annually to the best student During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements

Appointments —A House Surgeon is appointed annually. There are six men and two women Resident Pupils, and Clinical Clerks and Dressers are appointed from amongst deserving members of the class

Fees —Winter, six months, £8 8*s* , Summer, three months, £5 5*s* , nine months, £12 12*s*

For further particulars apply to Dr Bethel Solomons, Hon Sec., Medical Board, 42, Fitzwilliam-square

National Maternity Hospital, Holles-street, Dublin —Established 1894 The hospital consists of Intern and Extern Maternity, Gynæcological Wards, and a Dispensary for the treatment of Diseases of Women and Children During the year 1925–26, 1302 cases were admitted , 846 confinements took place in the hospital, and 342 gynæcological operations were performed In the district 653 confinements took place 6113 patients attended the dispensary for treatment Every facility is given for the carrying out of practical work Undergraduate and Post-graduate courses are arranged at any time Certificates of attendance at this hospital are recognised by all the licensing bodies Terms Undergraduate courses, 8 guineas for certified course (6 months), 3 guineas per month for uncertified course; Post-graduate courses, 3 guineas per month, 1 guinea for each extra week Clinical Lectures are given daily and Oral Lectures four times per week The L M Diploma is given by special examination which is held three times a year Entrance fee 1 guinea, certificate 4 guineas During the past year 98 graduates availed themselves of the Post-graduate courses Further particulars can be obtained from the Master, Dr P T McArdle, 27, Merrion-square , or from the Secretary, Holles-street, Dublin

Richmond, Whitworth, and Hardwicke Hospitals (House of Industry Hospitals), Dublin *—These hospitals contain 330 beds—130 for Surgical cases, 80 for Medical cases, 78 for Fever and other Epidemic Diseases, and an Auxiliary Wing of 42 beds A Resident Physician and a Resident Surgeon are appointed each half year and are paid for their services 20 Resident Clinical Clerks are appointed each quarter and provided with furnished apartments, fuel, &c These appointments are open not only to advanced students but also to those who are qualified in Medicine and Surgery The Dressers are selected from among the best qualified of the pupils without the payment of any additional fee Women students are eligible for election as residents and special apartments are reserved for their use For prospectuses apply to Mr Adams McConnell, F R C S I , Hon Secretary, 69, Fitzwilliam-square, Dublin

Rotunda Hospital, Dublin —This institution is the largest combined gynæcological and maternity hospital in the British Empire Over 4000 confinements are attended annually and 500 gynæcological patients admitted Students can take out their necessary gynæcological and midwifery practical courses The work of the hospital is carried on continuously through the year and consists of daily clinical instruction in the maternity department and examination and operations in the gynæcological department Qualified students are given facilities for studying and assisting in the management of all abnormal cases so far as is practical An antenatal dispensary is largely conducted by the senior qualified students of the hospital under the supervision of the staff A special class in gynæcological examination and diagnosis is conducted by the Assistants to the Master The appointments on the staff of the hospital are given to qualified past students of the hospital who have taken the L M and consist of Extern Assistants for six months, one being appointed every three months From these the Assistants to the Master are appointed Women students can reside in the hospital on the same terms as men The L M is granted by examination after a six months' course Fees for Intern students one month £6 6*s* , months other than the first £4 4*s* , three months £12 12*s* , six months £21 Special gynæcological class £2 2*s* per month For further particulars apply to the Master, Dr Gibbon FitzGibbon

Royal City of Dublin Hospital —Founded 1832 , enlarged 1851 , rebuilt 1893 135 beds There is a special wing for the treatment of fevers and contagious diseases founded by the late Mr Drummond Secretary W H Leadbeater There is a large nursery where special opportunities are afforded for the study of diseases of children, both medical and surgical There are also special wards for ophthalmic, aural, and gynæcological cases There is a largely attended out-patient department where students are allowed to attend accidents and dress cases under supervision. Six resident pupils are appointed every three months A House Surgeon and a House Physician are appointed annually

Royal Victoria Eye and Ear Hospital, Dublin.* —Established 1844 Incorporated 1897. 102 beds. In-patients, 1499 , out-patients, 8492.

Dr Steevens' Hospital, Dublin (Kingsbridge) —Established 1720 250 beds, only 150 now in use Patients, intern, 1197 , extern patients 7313 , extern dispensary attendances, including special V D Clinic, 44,529 There is accommodation for 10 resident pupils, each of whom is provided with a separate bedroom, and board is supplied by the hospital at a reasonable rate There is an Electric Massage Department and a " Sun-Ray " Department All information with regard to the terms for such residency can be had from the Resident Surgeon at the Hospital Secretary E D F Banks

St Vincent's Hospital and Dispensary, Dublin —Established 1834 200 beds Clinical Lectures in Medicine and Surgery are held from October to June. Special classes for Juniors from October to December. Pathological and Bacteriological Demonstrations are given every Thursday, and instructions in the use of Laryngoscope and Otoscope for Senior students every Saturday Medals and Prizes the Bellingham gold medal in Medicine and the O'Farrell gold medal in Surgery are offered for competition at the end of the summer session, as well as junior prizes, also the Surgeon McArdle Prize value £20 In the last term there was opened a new External Department and a new Pathological Laboratory Dr Meenan, Hon Secretary, 28, Fitzwilliam-square

We take this opportunity of thanking the officials of Government Departments and the Deans and Secretaries of the various institutions for their kind coöperation in enabling us to bring the information contained in our Students' Number up to date

LONDON: SATURDAY AUGUST 28, 1926

EXAMINATIONS.

It will be seen if reference is made to the explanatory note with which the Students Number starts that the first part of the Number deals with the various patterns by which qualification can be obtained for the legal practice of medicine The choice of career which depends upon such qualification should be guided by consultation of the articles which follow. dealing with the conditions of appointments in the State and Public Services and with the provisions for the qualified man to attend special courses and to pass special tests where success will give him the right or at any rate, a winning opportunity to obtain employment in accordance with his chosen bent Examinations as standardised by the G M C —how, when. and where they must be sat for, and what are the tests to be surmounted—form the general text of the main part of the Students Number, and we are reminded by various articles and letters in the press that physical and mental disorders may be associated with the struggles of a certain percentage of examinees And it is a truth that in the attempt to become doctors, some aspirants become patients We do not want to exaggerate the fact or to support the amiable family theory that when the name of one of its members is absent from a pass-list the condition of his or her health accounts satisfactorily for the catastrophe But on the other hand, these breakdowns among students, and especially among medical students. do occur under the nervous stress of impending examinations. the thing happens and should not be minimised Those in charge of the strenuous courses which precede our professional examinations will do well to keep the matter in mind We know that many examiners are influenced by a wise appreciation of the strain put upon a jumpy class of candidates but kindness cannot condone inability to respond to tests It is the inability which needs the preventive treatment of previous counsel

Five years ago the registration of medical students rose to the abnormal height of 3420, and there became reason for an apprehension that a point was being reached where the bulk of men and women requiring medical education could not be dealt with by the machinery in existence to say nothing of the implied threat to professional careers from the mere number of the entrants who would later have to live by the practice of their science and art Until that time those who conceived perpetually that the profession was overcrowded had few facts to support their theory they were being misled by the circumstance that there were certain centres where many doctors had congregated for various reasons and they conceived the local congestion and its resulting acute competition to be a general malady whereas it was only sporadic But the great recruiting of 1919, the reasons for which we can all surmise could not be viewed with equanimity. even by those who knew the old assertion of overcrowding to be largely incorrect for an unmistakable testimony to the public esteem in which medicine was held was becoming a practical embarrassment and justifying fear for the economic position A graph illustrating the figures (see p 480) indicates that the various factors which led to the multiplication of students have lost their force. and there is no reason to think that the medical profession will be overcrowded in the immediate future Further. we do not know that the unusual addition to the roll of qualified men, corresponding with the swelling of the students ranks has brought any undue consequences with it. even with the increased number of doctors that we now have the medical profession is not to-day redundant, for the amount of work that has to be done steadily swells as does the number of varying avenues which have to be traversed by the followers of medicine This is the fact which should be remembered when we are told dogmatically that examinations must be stiffened to keep out the weaker candidates Things are not as simple at the threshhold of a learned profession as they are at the doors of a test match On these occasions unusual barriers can be erected and stringent measures taken to regulate ingress when too many persons are expected And the precautions have a logical effect Access to entertainments is strictly guarded in defence of those who have paid their money—translated into terms of examinations, for those who have learned their work But examinations especially in such a far-ranging collection of subjects as medicine do not play the same practical rôle A serious proportion of those who have paid with their industry and intelligence for the opportunity to enter the qualified ranks do not succeed assuredly or promptly, and it is this high element of uncertainty which conduces to the failure of nervous students No general relaxation of standard is desired from the authorities while, from the economic aspect a stiffening can be justified on public grounds by the satisfactory number of candidates but the ideal part which the examinations should play in the curriculum has not yet been found, despite repeated and real research And the uncertainty of the results of these tests does affect some examinees seriously.

We can welcome our recruits with the assurance that there is plenty of work for them to do, and we can congratulate them because that work has to be done in every section of professional endeavour in fairer and more generous circumstances than used to prevail in times not far away With regard to contract practice, hope lies in that betterment of organisation which experience is bringing. and which has been in the minds of many since the passage of the National Insurance Acts. the position does not promise to improve pecuniarily and consolation must be sought in the reflection that, as such practice stands at present, it is hugely better in its material results than it was 20 years ago when it was admittedly scandalous The Services only in the last few weeks, have made drastic revision of their regulations in favour of their medical staffs, and the authorities at medical schools will certainly have noted the opportunities now offered to their pupils Elsewhere salaries have risen and medical officers. though poorly paid in comparison with those who discharge other public duties receive better terms and their terms have not been wholly dictated by the general rise in prices but have followed on a wider appreciation by the public of the meaning and value of preventive treatment and organised therapeutics These are solid reasons for congratulating our students upon their choice of a career If entrance to the arena is fenced around with difficulties there is zest in the surmounting of these And the return for success is not the pleasure of looking on, but the privilege of playing

NAVAL MEDICAL SERVICE

IN the Navy the young medical officer sees the world in congenial company and with an assured position, the pay is good, the pensions are commensurate, and the opportunities offered now for scientific work are real, while, if they are taken, promotion awaits the officer on grounds of professional merit

As a result of the recommendations of the Inter-Departmental Committee on the Medical Branches of the Fighting Services, the following changes in the conditions of service have been approved. These changes were designed to take effect from July 1st, 1926, and will do so as soon as the necessary arrangements can be made —

(1) *Increase in the Establishment of Surgeon Captains* The maximum number of Surgeon Captains authorised to be borne will be increased from 16 to 20 Two Surgeon Captains will be appointed to the R N Hospital, Haslar, as Professors of Medicine and Surgery, respectively, on instructional duties connected with the general courses described below The appointment of Director of Medical Studies, Naval Medical School, R N College, Greenwich, will in future be held by a Surgeon Captain, and a Surgeon Captain will be appointed to the R N Hospital, Malta, as second in charge

(2) *Increase in Specialists' Allowances and Number of Appointments* —The number of Specialist appointments will be increased from 46 to 60, and the new appointments will include Specialist posts in Medicine, Surgery, Radiology, and Hygiene The allowance payable to holders of Specialist appointments will be increased from 2*s* 6*d* to 5*s* per day, as from July 1st, 1926

(3) *Grant of Charge Pay* —The grant of charge pay will be made as from July 1st, 1926, on the following scale for Medical Officers in charge of hospitals and sick quarters Surgeon Rear-Admirals and Surgeon Captains, 10*s* a day, Surgeon Commanders, 5*s* a day

(4) *Professional Courses* —(*a*) *General Courses* Every Officer below the rank of Surgeon Captain, except when he has just vacated an appointment at a Home Hospital or is due to take his promotion course, will be appointed, if his services can be spared, once in every four years to the R N Hospital, Haslar, for a course of instruction of not less than four months' duration in Clinical Medicine and Surgery and allied subjects At the end of the course, instead of being placed on Unemployed Time, the Officer will be appointed for duty at one of the R N Hospitals at Haslar, Chatham, or Plymouth, unless or until he receives an appointment elsewhere (*b*) *Specialist Courses*. Every Officer selected to hold a Specialist appointment will, provided his services can be spared, undergo a course of not less than six months' duration in his special subject at a civil hospital in London or other teaching centre, and will subsequently undergo a course of three months' duration in that subject every four years while he is employed as a Specialist (*c*) *Senior Medical Officers' Courses* The existing Senior Medical Officers' Courses will to a large extent be superseded by the General and Specialist Courses described above, and their number will therefore be capable of reduction without detriment to the professional opportunities in the Service, but the reduction will not be made until the new courses have been in operation for some years The institution of General and Specialist Courses will necessitate an increase in establishment, and they cannot therefore be put into full operation until this increase has taken place, but the new arrangements will be inaugurated as soon as possible

(5) *Time in Hospital Appointments* —In the case of Officers entering the Naval Service on or after July 1st, 1926, the following rules for counting time in hospital appointments will apply —

An Officer who enters the Service on or after July 1st, 1926, and who has held, for a period of not less than one year before the date of his entry into the Service, a resident appointment as Medical or Surgical Officer in a civil hospital after becoming a qualified medical practitioner, to be eligible, at the discretion of the Admiralty, to have his seniority antedated by not more than one year, provided that the appointment is one recognised by the Admiralty for this purpose, but this concession will not ordinarily be granted where the interval between the termination of the hospital appointment and the date of entry into the Service exceeds six months The period of not less than one year in a "resident" appointment may, at the discretion of the Admiralty, include a period of not more than six months spent in a "non-resident" appointment recognised by the Admiralty

The increase of seniority allowed under the above conditions shall not render an Officer eligible to receive pay before the date of his actual entry into the Naval Service, but the time concerned shall reckon for increase of full, unemployed and half pay while on the active list, and retired pay or gratuity on retirement or withdrawal, provided in the case of a gratuity, that the Officer has completed three years' full pay service in the Royal Navy, that is, exclusive of the time spent as Resident Medical or Surgical Officer in a civil hospital

In the event of a temporary Officer, or an Officer entered for short service (*v infra*) being transferred to the permanent list on or after July 1st, 1926, he may be granted the above concession, at Admiralty discretion, under similar conditions to those applicable to candidates who may enter the permanent service direct, except that the time shall not count for gratuity on retirement or withdrawal

A candidate who is over the normal age limits for entry may be entered, notwithstanding provided that the period of antedate for which he is eligible brings him, if deducted, within the ordinary limits

Rank of Surgeon Lieutenant-Commander will be granted to surgeons at the expiration of six years from date of entry, and the point upon which stress should be laid is that special promotion can be made in cases of conspicuous professional merit, which is thus placed on a par with general service Six years later the period of promotion to Surgeon Commander is reached, after the qualifying examination has been passed, when again special promotions can be made for conspicuous professional merit as well as for distinguished service ; but promotions are limited in number, save, of course, for gallantry in action This recognition of professional attainment should prove a very real incentive to progressive scientific work The same principle prevails in the higher ranks. Promotions to Surgeon Captain and later to Surgeon Rear-Admiral are made strictly by selection, but are confined to officers who prove fitted, both professionally and as administrators, for this rank

Naval life may lead to opportunities for putting into practice much of what has been learned in the clinical wards of a hospital Further, the opening for preventive medicine is large and many-sided, while appointments to the large shore establishments enable medical officers to keep their work modern New chemical explosives as well as the extraordinary behaviour of common articles under extraordinary conditions of stowage, furnish perpetual problems and surprises for the medical officer The health lectures which he is bound to deliver will often afford a starting point of work that may develop into great professional interest Numerous changes have been introduced during the last 20 years into the naval dietary, many of which were the outcome of representations and research by naval medical officers The work wants carrying on, for much of it has gone to show that the food problem is very complicated. Every medical officer on board ship should make himself acquainted with food values and the human powers of assimilation under varying conditions of work and climate, and here there is ample scope for research The modern requirements of gunnery and navigation necessitate precision in their use and have made ophthalmology a valuable subject for study in the Navy. The physical training of both officers and men is based on physiological axioms which are peculiarly the field of the medical officer. Lastly, there is the whole field of venereal and tropical disease

The young medical officer need not be afraid that his work will be without scientific interest if he takes the opportunities offered him.

Conditions of Service.

The rates of pay of the Medical Service are subject to periodical revision in the light of the cost of living, and it is necessary to indicate as closely as practicable the extent and methods of the periodical revision.

In order that students may be under no misapprehension regarding their remuneration should they decide to join the Naval Medical Service, it should be clearly understood that when the pay of naval officers was revised in 1919 it was definitely laid down that 20 per cent of the rates of full pay, unemployed pay, half pay, and retired pay was to be considered as due to the high cost of living in 1919, and that it should be subject to change periodically either upwards or downwards according as the cost of living rose or fell. The first revision took place in July, 1924 when all the rates were reduced by approximately 5½ per cent. and further revisions (not necessarily reductions) are due every three years—i e in July, 1927, July 1930, and so on.

The pay of the Naval Medical Service is shown in two tables one showing the scale introduced in 1919, which is described as the standard rates and of which 20 per cent is variable, and the other showing the actual scale in force from July 1st, 1924, to June 30th 1927

For the time being the regulations for entry by examination into the permanent service are in abeyance, but a short-service scheme providing for transfer to the permanent service has been inaugurated. The regulations for the entry of surgeon lieutenants under this scheme provide for the usual qualifications of registration, good character physical fitness, and age—the age not to exceed 30 years The conditions of service are a three years' engagement with an option of a further year, to serve when and where required under the general rules of the service as regards discipline, and to rank with, but after, surgeon lieutenants in the permanent service, and to receive two calendar months' notice of services being no longer required.

As from July 1st, 1924, the pay is £1 5*s* (standard rate £1 6*s* 6*d*) per day or £456 5*s* (standard rate £483 12*s* 6*d*) per annum while there is a gratuity, not subject to variation with the cost of living, on discharge of £8 6*s* 8*d* for each completed month of service All officers during service are accommodated and victualled on the usual service scale or receive lodging money and provision allowance in lieu, at rates subject to periodical revision. The present rates of lodging money and provision allowance are £80 and £55 a year respectively Unlike permanent officers medical officers entered for short service are not liable to periods of unemployment on unemployed or half pay or eligible for retired pay in respect of service If however such an officer were invalided for a cause certified by the competent naval medical authority as attributable to the conditions of service, he would be eligible for disability retired pay in lieu of the gratuity on discharge referred to above Similarly in the event of his death from a cause attributable to the service his widow and children would be treated in the same manner as the widow and children of an officer on the permanent list There is an equipment allowance for ordinary uniform of £50, but the officer provides himself with a pocket case of instruments and a stethoscope

A short-service surgeon lieutenant after six months' service, on application to the Secretary of the Admiralty, may be considered for transfer to the permanent service on a satisfactory report being received from the senior medical officer of the Squadron, Hospital or Depôt in which he has served or is serving as to his professional ability, and a favourable report from his commanding officer as to conduct. Such candidates must have been under the age of 28 on joining for short service, and officers so transferred will not be eligible for the gratuities provided They will be permitted to count their seniority from date of entry for short service for purposes of promotion and for increment of full pay, and similarly they will be permitted to count their service from the date of entry for purposes of retired pay, but for purposes of retiring gratuity on the permanent officers' scale their services will be reckoned only from the date of transfer to the permanent list, this date being that of receipt in the ship or establishment in which the officer is serving of the order for his transfer to the permanent list Until that date he will retain his temporary rate of pay.

If a short-service lieutenant transfers to the permanent service he will then come under the following conditions of pay and pensions.—

Standard and Present Rates of Pay

Rank	Standard rate						Rate from July 1st, 1924					
	Year of 365 days			One day			Year of 365 days			One day		
	£	*s*	*d*	£	*s*	*d*	£	*s*	*d*	£	*s*	*d.*

Surg Rear-Admiral	1916	5	0	5	5	0	1809	15	10	4	19	2

On first appointment to the Service, medical officers will receive full pay from date of appointment, but subject to the provisions of Article 1347 of the King's Regulations.

Officers of the permanent service are eligible during periods of unemployment for unemployed pay and half pay The rates of unemployed pay and half pay, and the conditions under which they are granted are the same as in the dental branch and are set forth in detail later in this article

Flag Allowances

An allowance of 5*s* a day in addition to full pay is granted to the Senior Medical Officer of a flagship bearing the flag of a Commander-in-Chief An allowance of 2*s* 6*d* a day is granted to the Senior Medical Officer of a ship bearing other flags or broad pendants.

Standard Rates of Retired Pay

Compulsory retirement will be as follows.—

(i) Surgeon Rear-Admirals retire at the age of 60 with retired pay at the rate of £900 per annum plus £22 per annum for each year's service over 27 years counting for retired pay subject to a maximum rate of £1010 per annum. If however, less than 27 years' service counting towards retired pay is rendered a deduction of £22 per annum is made for each full year wanting to complete that period, subject to a minimum of £700 per annum

(ii) Surgeon Captains retire at the age of 55 Maximum retired pay, £900

(iii) Surgeon Commanders retire at the age of 50 Maximum retired pay, £700

(iv) Surgeon Lieutenant-Commanders and Lieutenants retire at the age of 45 Maximum retired pay, £450

Subject to these maxima, the rates of retired pay for Surgeon Captains, Surgeon Commanders, Surgeon Lieutenant-Commanders, and Surgeon Lieutenants are as follows —

Age on retirement	Retired pay	Period of service (years) counting towards retired pay	(A)		Age on retirement	Retired pay	Period of service (years) counting towards retired pay	(A)	
			Addition	Deduction				Addition	Deduction
	£ (p a)		£ (p a)	£ (p a)		£ (p a)		£ (p a)	£ (p a)
55	790	24	22	15	47	562	20	15	15
54	765	24	22	15	46	525	20	15	15
53	742	23	22	15	45	487	19	15	15
52	720	23	22	15	44	450	19	15	15
51	697	22	22	15	43	412	18	15	15
50	675	22	15	15	42	375	18	15	15
49	637	21	15	15	41	337	17	15	15
48	600	21	15	15	40	300	17	15	15

(p a) = per annum

(A) Addition for each full year's service in excess of that specified in column 3 or deduction for each full year wanting to complete that period of service—addition or deduction limited to five years in each case

Twenty per cent of all the rates of retired pay referred to above is variable with the cost of living, and the rates at present in course of payment are approximately 5½ per cent below those given above

DENTAL BRANCH

1 The Naval Dental Service offers similar opportunities to qualified dental surgeons except that higher rank than that of the recently instituted Surgeon Captain (D) is not open to them They are provided with suitable surgery accommodation equipped with modern appliances and supplied with all material required for their work and there is every opportunity for them to maintain a high standard of professional skill

2 Candidates are required to produce certificates of birth, registration, and of character, and must be physically fit for active service anywhere An outfit allowance of £50 is payable to officers finally entered and commissioned The rank of Surgeon Lieutenant-Commander (D) is attained on the completion of six years' satisfactory service Promotions to Surgeon Commander (D) and Surgeon Captain (D) are made strictly by selection from the rank next below and are confined to officers who prove fitted in every respect for these ranks The present establishment of dental officers is 1 Surgeon Captain (D), 3 Surgeon Commanders (D), 60 Surgeon Lieutenant-Commanders (D) and Surgeon Lieutenants (D)

3 Provision has been made for candidates who, at the time of passing the examination, hold or are about to hold an appointment as Dental Officer in a recognised Civil Hospital The time concerned, provided it does not exceed six months, may reckon for increase of full pay while on the active list Surgeon Lieutenant-Commanders (D) of over two years' seniority will be eligible for a three months' Post-graduate Course while borne on full pay

4 As in the case of the medical branch, 20 per cent of the rates of full pay, unemployed pay, half pay, and retired pay introduced in 1919 is considered as due to the high cost of living in 1919 and subject to change periodically either upwards or downwards according as the cost of living rises or falls The first revision took place in July, 1924, when all the rates were reduced by approximately 5½ per cent, and further revisions are due every three years—i e in July, 1927, July, 1930, and so on The following table and paragraphs show the standard rates introduced in 1919, of which 20 per cent is variable and the present rates which will operate from July 1st 1924, to June 30th, 1927 The rates of full pay and half pay, &c of the Surgeon Captain (D) are not at present available but with regard to other ranks they are as follows —

Full Pay

Rank	Standard rate						Rate from July 1st, 1924					
	Year of 365 days			One day			Year of 365 days			One day		
	£	s	d	£	s	d	£	s	d	£	s	d
Surg Lieut (D) on entry	401	10	0	1	2	0	380	4	2	1	0	10
After 3 years	492	15	0	1	7	0	465	7	6	1	5	6
Surg Lieut Comdr (D) on promotion	593	2	6	1	12	6	559	13	4	1	10	8
After 3 years	629	12	6	1	14	6	596	3	4	1	12	8
„ 6 „	666	2	6	1	16	6	629	12	6	1	14	6
„ 9 „	730	0	0	2	0	0	690	9	2	1	17	10
Surg Comdr (D) on promotion	775	12	6	2	2	6	733	0	10	2	0	2
After 3 years	848	12	6	2	6	6	803	0	0	2	4	0
„ 6 „	921	12	6	2	10	6	869	18	4	2	7	8
„ 9 „	994	12	6	2	14	6	939	17	6	2	11	6

On first appointment to the Service, Dental Officers will receive full pay from the date of appointment, but subject to the provisions of Article 1347 of the King's Regulations, 1913

Dental Officers are eligible for the same rates of lodging and provision allowances as other officers of equivalent rank and are entitled to the same privileges The rates of half-pay are —

Unemployed Pay and Half Pay —A distinction is to be drawn between—

(*a*) Officers awaiting employment

(*b*) Those who are permitted for private reasons which the Admiralty regard as satisfactory to refuse an appointment or to have their appointment cancelled or who are unemployed at their own request or in consequence of misconduct

In the former case—

(*a*) Officers are to receive unemployed pay as follows —

For the first six calendar months full pay of rank (without allowances)

For the next six calendar months —

Rank	Standard rate per diem			Rate per diem from July 1st, 1924		
	£	s	d	£	s	d
Surgeon Lieutenants (D)	0	17	0	0	16	0
Surgeon Lieutenant Commanders (D)	1	2	6	1	1	3
Surgeon Commanders (D)	1	7	6	1	6	0

Thereafter —Half the full pay of their rank and seniority on the Executive Officers' scale, namely —

Surgeon Lieutenant (D)	0	8	6	0	8	0
„ „ of 4 years' seniority	0	10	0	0	9	5
Surgeon Lieutenant Commander (D)	0	15	0	0	14	2
„ „ of 3 years' seniority	0	16	0	0	15	0
„ „ of 6 years' seniority	0	17	0	0	16	1
Surgeon Commander (D)	1	0	0	0	18	11
„ „ of 3 years' seniority	1	2	0	1	0	9
„ „ 6 „ „	1	4	0	1	2	8
„ „ 9 „ „	1	6	0	1	4	7

Unemployed pay will not, however, be granted in cases where an officer is undertaking continuous professional work for which payment is made

In the latter case, (*b*), Officers may receive half the full pay of their rank and seniority on the Executive Officers' scale

Periods during which unemployed Full Pay or Unemployed Pay are received will only count as half-pay time—that is, as one-third of full service

An Officer who is permitted, for private reasons, to decline an appointment, or to have his appointment cancelled will not be entitled to any Unemployed Pay In such cases, Officers may be placed on Half-Pay

The conditions of retirement, Widows' Pensions, Leave, &c, are the same as for medical officers of equivalent rank and seniority

Arrangements are also made whereby officers may be allowed to withdraw from the Service after four years' service and receive gratuities on the following scale :—

Gratuities will be awarded on retirement and withdrawal on the undermentioned scale

Rank		Gratuity £	s	d
Surgeon Lieutenant (D), Surgeon Lieutenant-Commander (D), and Surgeon Commander (D)				
After 4 years' full-pay service		500	0	0
„ 8 „ „	including service allowed by paragraph 3	1000	0	0
„ 12 „ „		1500	0	0
„ 16 „ „		2250	0	0

ARMY MEDICAL SERVICE.

ROYAL ARMY MEDICAL CORPS

THE publication of a new Royal Warrant on June 29th 1926 has gone a long way towards removing the alleged grievances of officers of the Corps and this Service can again be recommended as a career to young medical men Competitive examinations for regular commission, which have been in abeyance for some time will again be held half-yearly in January and July. These examinations in medicine and surgery are entirely of a clinical and practical character, partly written and partly oral

The regulations for admission giving full details should be obtained from the Under Secretary of State (A M D 1) War Office, Whitehall London, S W 1 and carefully studied A personal interview with a representative of the Director-General, Army Medical Services is readily obtainable

The rates of pay and allowances are good, the opportunities of post-graduate study are generous, and the work is varied responsible, and interesting The gratuities after certain periods of service enable an officer should he so desire to leave the Service with a capital sum large enough to go a long way towards re-establishing himself in civil life and further, the knowledge of the world and the comradeship of his fellow officers that he has gained in the Army will be of no small value to him

New entrants are commissioned in the rank of Lieutenant, and the first six months of service are spent on probation during which time they undergo in addition to their Military training at the Royal Army Medical Corps Depot at Aldershot a probationary course at the Royal Army Medical College in London in Hygiene Pathology Tropical Medicine. Military Surgery Recruiting the prevention and treatment of Venereal Disease, and the elements of Army Administration At the end of this course and after qualifying at the necessary examinations their commissions are confirmed and they take their places in seniority according to the total marks obtained at all examinations up to that date Officers Training Corps service with possession of Certificates A' or B (Medical) carry a definite value in marks in this total

An entrant who is holding or about to hold at the time of the entrance examination a resident House Appointment at an approved Civil Hospital may be seconded while holding such an appointment up to a maximum period of 12 months A candidate who has held such an appointment within six months of entry may be granted an antedate up to 12 months in respect of the period the appointment was held This secondment and antedate counts in all respects as commissioned service except that pay will not be issued for that period

After a total period of one year s service at home the young officer goes abroad probably to India, for his first tour of foreign service Here he gains his first practical experience of tropical disease and tropical hygiene and possibly his first experience of active service on the frontiers of India His tour abroad lasts five years with probably six months' leave home during that time On returning home the R A M C officer has the opportunity to decide whether he will remain in the Corps or accept the gratuity of £1000 after seven years' service and try his fortune in civil life If he elects to remain he will between his eighth and twelfth year of service undergo a course of post-graduate study at the Royal Army Medical College and the London Hospitals of five months' duration, followed by a course of study of a special subject selected by himself, provided he has shown special aptitude in the post-graduate course or during his previous service During this period of study he remains on full pay and the fees for the courses are paid by the State. When qualified in his special subject the officer becomes entitled to specialist pay at 5s per day when holding a specialist appointment After this post-graduate course the officer probably proceeds abroad again and promotion to Major rapidly ensues and from that time onward the officer receives regular successive increases of pay, and is eligible for additional and charge pay as well. The Directorates of Hygiene and Pathology and the appointment of two serving officers as Consultants in Medicine and Surgery have been instituted and have proved a marked success all these appointments being of the rank of Colonel or Major-General.

Under these conditions the possibilities for good workers are very great in the Royal Army Medical Corps There is scope for original research in tropical disease, in preventive medicine and in bacteriology, as well as in the large clinical field open to the specialist in Medicine Surgery or Gynæcology, in Venereal Disease and in Ophthalmology Child welfare is also undertaken systematically by officers of the Royal Army Medical Corps

At the same time instruction in administration is continuous The Royal Army Medical Corps is essentially organised for war, and one of the lessons of the Great War was that trained administrators must exist to enable the fullest benefit to be obtained from professional talent Many appointments carrying administrative responsibility are open to those officers who display capacity for this duty All officers must be prepared to undertake command and to have a knowledge of Army administration especially in war. Equally important is the technical training of the Non-commissioned Officers and men of the Corps in such ' trades ' as Trained Nurse Nursing Orderly. Masseur Radiographer. Operating Room Assistant Laboratory Assistant Hospital Cook Dispenser &c This training is carried out by the Officers and Nursing Sisters and opens a large field for those who have ability in lecturing and teaching as well as the power of influencing men

Promotion

Promotion takes place automatically to Captain after 3½ years and to Major after 12 years service, provided the officer is qualified and recommended for promotion Promotion to the higher ranks is by selection from those senior in the rank below but special promotion by brevet or otherwise is open to officers of the Royal Army Medical Corps

Additional Pay and Charge Pay for Officers of the R A M C.

(1) Officer not above the rank of lieutenant-colonel, while acting as specialist in a post considered by Our Army Council to merit the grant of additional pay, according to subjects or groups of subjects as under

Operative Surgery advanced Medicine, Ophthalmology Gynæcology and Midwifery Dermatology, and Venereal Disease Otology, Laryngology, and Rhinology, Radiology, Anæsthetics, Mental Diseases, Hygiene, Pathology; subjects other than above, at the discretion of Our Army Council 5s daily

(2) (a) Officer in charge of a hospital —If the number of equipped beds as certified by the Deputy Director of Medical Services exceeds—

50 beds	. 2s 6d daily	300 beds	7s 6d daily.
150 „	3s 0d „	500 „	10s 0d „

Officer in charge of a medical or surgical division of a general hospital with not less than 300 beds—half the above rates

	Daily. s d
(b) Senior medical officer, Royal Arsenal, not exceeding	10 0
(c) Officer in command of the depôt, Royal Army Medical Corps	5 0
(d) The senior officer of the Army Medical Services with an army in the field A rate to be fixed by the Army Council according to the magnitude of the charge	
(e) The officer, if under the substantive rank of colonel, holding the appointment of senior medical officer in a command abroad, or of assistant director of medical services, if the number of soldiers is 1500 or upwards	5 0
(f) Adjutant R A M C Depôt	5 0
(g) Adjutant R A M C (Territorial Army)	2 6

The Army Dental Corps

The Corps is administered by the Director-General, Army Medical Services It is a joint service for the Army and Royal Air Force and personnel is required to serve under either force and be interchangeable Officers and other ranks posted for duty with the Royal Air Force will perform their duties under the Regulations of the Royal Air Force for the employment of dental personnel, but the conditions in the following tables apply equally in either force Promotion is carried out on one general list The regulations for admission to the Army Dental Corps should be obtained from the Under-Secretary of State, War Office, and carefully studied.

c s =commissioned service

* Pay Warrant rates as amended by A O 196/26 less 5½ per cent from July 1st, 1924, vide A O 93 and 204 of 1924 The Pay Warrant rates are subject to revision to an extent not exceeding 20 per cent according to variation in the cost of living The next revision takes place from July 1st, 1927

† Rates of allowances vary from time to time and issues are subject to conditions laid down in the Allowance Regulations

Retirement and Retired Pay.

The following are the rates of pension and retired pay —

1. Retired pay will consist of two parts (a) a service element based on the officer's total service, (b) a rank element for the rank from which the officer retires An officer with less than 20 complete years' service will not be eligible for retired pay

2 The scale will be as follows, subject to the reduction of 5½ per cent referred to below —

(a) Service element —£15 a year for each completed year of service as a medical officer

(b) Rank element —

Rank from which retired	After completing 1 year's service in the rank	After completing each additional year's service	Maximum rank element
	£	£	£
Major	12	12	120
Lieutenant - Colonel	150	30	240
Colonel	290	50	390
Major General	440	50	540
Lieutenant - General	590	50	690

The retired pay of an officer retiring with less than one complete year's service in the rank from which he retires will be assessed as though he had retired from the rank below

Maximum rates of retired pay (a) and (b) together —

	£		£
Captain and Subaltern	300	Colonel	800
Major	450	Major-General	1000
Lieutenant-Colonel	600	Lieutenant General	1200

The above rates are those laid down in the Pay Warrant They have been reduced by 5½ per cent as from July 1st, 1924

3 Officers with seven and less than 20 years' service as medical officers may be permitted to retire with a gratuity in accordance with the following scale —

After 7 years' service as a medical officer	£1000
" 3 " " in the rank of Major	£2800
" 6 years' service as a medical officer in the rank of Major	£3500

Officers *Appointment and Promotion*

1 Commissions as Lieutenants in the Army Dental Corps may be given to persons duly qualified under regulations approved by the Army Council

2 An officer shall be eligible for promotion to the rank of Captain on completion of three and a half years' service and to the rank of Major on completion of 12 years' service in the Corps, provided he has previously qualified in such manner as may be prescribed by the Army Council

3 Promotion to the rank of Lieutenant Colonel and Colonel to fill the establishments laid down from time to time for those ranks, shall be made by selection of the Army Council, provided the officer has previously qualified for promotion to those ranks in such manner as may be prescribed by the Army Council

4 Appointments are in the rank of Lieutenant, except in cases where service of three and a half years or more has been given as a temporary dental officer when the rank of Captain will be given Service as a temporary dental officer will count towards the three and a half years for promotion to Captain, and the 12 years for promotion to Major

Pay

The following are the rates for officers of the Army Dental Corps —

	Per diem £ s d
Lieutenant	0 18 10
Captain	1 3 8
Captain after 8 years' total service	1 6 8
Captain " 10 " " "	1 8 4
Major	1 13 0
Major, after 15 years' total service	1 17 10
" " 18 " " "	2 0 2
" " 20 " " "	2 4 10
Lieutenant-Colonel	2 12 0
Lieutenant-Colonel after 3 years' service as such	2 16 8
Colonel	3 3 10

These rates are 5½ per cent *below* those shown in the Pay Warrant, 1926, as amended by Army Order 196/26 The latter are subject to revision to an extent no

20 per cent according to variation in the cost of living. The next revision takes place on July 1st 1927.

Charge Pay

The officer in charge of the Dental Laboratories, Aldershot, receives charge pay at the rate of 5s a day if holding the rank of Captain, or 2s 6d a day if holding the rank of Major.

Allowances

The allowances for officers of the Army Dental Corps are at the same rates as for officers of the Royal Army Medical Corps.

Retirement and Retired Pay or Gratuity

(1) The rates of retired pay will be the same as for officers of the Royal Army Medical Corps.

(2) Voluntary retirement on retired pay will not be allowed until after twenty years' service.

(3) Earlier retirement on gratuity may be allowed —

After 8½ years'	service as a Dental Officer	gratuity of £1000
" 15 "		" £2000
" 18 "		" £3000

(4) Retirement will be compulsory at the age of 55 years.

(5) A lieutenant who does not qualify for promotion within three and a half years' service in the Corps will be retired, and a captain who fails to qualify for promotion to major within twelve years' service in the Corps will be retired on any gratuity for which he may be eligible under paragraph 3.

The aim of the Corps is the prevention of wastage of man power on account of dental disease or dental deficiency, and, to enable this to be carried out, every recruit is inspected by a dental officer immediately after joining and all necessary treatment carried out. The soldier will be re-inspected at least once a year and his dental efficiency maintained at the best standard possible. As recruits are not now enlisted unless they have sufficient natural teeth to enable them to masticate efficiently it is hoped that the conservative nature of the treatment they will receive will reduce considerably the percentage of artificial dentures required.

INDIAN MEDICAL SERVICE

THE entry of European medical candidates into the Indian Medical Service practically ceased with the last open competitive examination held in 1915 and it is an open secret that recruitment for the Service had for many years previous not been brisk with the result that at the present time the Service is well officered in its higher ranks and notably deficient in the ranks of those who will be called to succeed them. Among the senior and retired officers are many whose work in medicine and the allied sciences has become a household word for a generation ago the conditions of service were such as to attract men of the greatest promise in the medical schools who were rarely disappointed in a career which, without producing wealth gave unlimited opportunity for the display of talent in research and administration unfettered by irksome restriction. We may suppose, and it is the view of many senior officers in the Service that the period of depression is now passing and that the prospect is again bright for those who are fitted in physique and disposition for a medical career in India.

But the new outlook involves frank acceptance of the Indian reform scheme the essential of which is increasing participation of Indian-born subjects in the government of the country although so long as Europeans are employed in the various departments of the Indian Civil Service nothing is more certain than that there will and must remain European doctors to attend them. Entrants must also be prepared to face the fact that more time will elapse before they can hope to get into civil employ and that opportunities for private medical practice are not what they were. On the other hand it is reasonably certain that the social effect of Indianisation will not press hardly on the medical service for the reason that European doctors will be chiefly requisitioned in stations with considerable European communities. In these communities the equipment and organisation of hospitals has been steadily improving and men with professional ambition will find positions which will satisfy their aspirations. On the military side the station hospital system has rendered the position of medical officers more independent by making team-work possible and permitting of specialisation in various departments of medicine and surgery. Lastly, those who join now will have unequalled prospect of advancement in a Service which has been so depleted for 10 or 15 years or more, and the new terms of service announced by the Secretary of State for India last month assure conditions of pay pension and furlough much superior to those recently offered.

Special Recruitment

To meet the immediate need the offer has been announced of special terms for permanent commissions to a small number of medical men of European descent free to sail for India within the next few months. Candidates, who must be well qualified and between 21 and 32 years of age, will be appointed on the nomination of a selection committee before whom they will appear in person. The special advantage offered is the option of retirement on a gratuity at the end of a short specified period of service—£1000 after six years £2500 after 12 years—and if the option is not taken up the officer will continue in the Service on the ordinary pensionable footing. They will be eligible for the concessions granted in the new provisional regulations and for free passage if invalided home on sick leave during the first 12 years. Military employment only is guaranteed but they will enjoy the benefits of any conditions regarding civil employment applicable to officers appointed later to the Service as a result of decisions taken on the Lee Commission report.

The New Provisional Regulations

Competitive examination remains suspended for the present and admission to the Service is on written application to the India Office. As sound bodily health is a first essential candidates may if they wish it undergo a preliminary examination by a Medical Board which meets weekly at the India Office.

Candidates must be under 32 years of age at the time of application and possess qualifications registrable in Great Britain. Up to the present time officers have been employed both in civil and military departments and have been interchangeable between the two. At the beginning of his career an officer was employed on the military side, which has medical charge of the Indian Army. If he remained in military employ he held a post on the staff of a station hospital or a specialist post, or a post on the administrative staff of the army promotion being on a time-scale up to the rank of lieutenant-colonel and by selection to the ranks of colonel and major-general. He could however if he chose apply, after two years' Indian military service to be registered as a candidate for transfer to the civil side from which appointments are made to civil surgeoncies established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes and to the specialist services (for example public health bacteriological and research departments, and the professorships at the medical schools). Such transfers normally took place after about seven years service in military employment. In view however of the recommendations of the Lee Commission only military employment can be guaranteed to officers entering at the present time although they will be eligible for such civil employment as may become available as a result of the Lee Commission report. Executive medical officers in both civil and military employment may attend persons unconnected with Government service provided their duty admits of it. On the military side however the opportunities for private practice are not great. Service during the war as a medical or combatant officer, or in a position usually filled by an officer, counts towards promotion and pension so long as the rights of officers who have entered by competition are not interfered with

Rates of Pay

The monthly rates of pay for European officers in the Service are as tabulated below The rupee, it should be remembered, has just been stabilised at 1*s* 6*d*

Rank and service in rank	Basic pay	Overseas pay		Year of total service
		If drawn in sterling	If drawn in rupees	
	Rs	£	Rs	
Lieut	500	—	150	First
		—	150	Second
		—	150	Third
Captain —				
1 During first three years' service as Captain	650	—	150	Fourth
		15	150	Fifth
		15	150	Sixth
2 With more than three and less than six years' service as Captain	750	25	250	Seventh
		25	250	Eighth
		25	250	Ninth
3 With more than six years' service as Captain	850	25	250	Tenth
		25	250	Eleventh
		30	300	Twelfth
Major —				
1 During first three years' service as Major	950	—	—	—
2 With more than three and less than six years' service as Major	1100	—	—	—
3 With more than six years' service as Major	1250	30	300	Thirteenth and over
Lieut Colonel —				
1 Until completion of 23 years' total service	1500	—	—	—
2 During twenty-fourth and twenty-fifth years' total service	1600	—	—	—
3 After completion of 25 years' total service	1700	—	—	—
4 When selected for increased pay	1850	—	—	—

Note —Until the completion of 23 years' total service basic pay is regulated according to rank and service in rank (column 1) which, owing to the system of accelerated promotion, may be in advance of the time scale of promotion Overseas pay is regulated solely with reference to length of total service (column 5) In addition to grades there are a number of appointments as colonels on Rs 2200 to Rs 2500, according to the appointment held, and as major general on Rs 2750 The appointment of Director of Medical Services in India, carrying pay at Rs 3200 per mensem, may also be held by an officer of the Indian Medical Service

Initial rates of pay are based on the assumption that the majority of newly appointed officers will be bachelors An officer, when junior, is liable to more frequent changes of station than later on in his service, and he may therefore be put to considerable expense for transfers if he has a family Officers who are married before joining may find difficulty in living within their pay during the first few years of their service Officers in military employment, when in command or second-in-command of the larger station hospitals, receive special allowances On the civil side there are public health, bacteriological, research, and professorial appointments carrying special enhanced rates Special rates of pay are attached to administrative appointments Officers on appointment receive an outfit allowance of £50

Pensions and Allowances

The rates of pensions are as shown in the table below

There are additional pensions not subject to the above reduction ranging from £125 to £350 per annum for officers who have held high administrative appointments as colonels or major-generals

Officers on appointment are, when possible, provided with passage to India by transport When such accommodation is not available passage is provided by private steamer, or passage allowance granted if preferred The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be given free passage to India Officers are granted a certain number of return pasages home at Government expense during their career. There are special allowances for officers whilst on study leave.

Service	Rates per annum	Service	Rates per annum
After 17 years	£400	After 23 years	£620
„ 18 „	430	„ 24 „	660
„ 19 „	460	„ 25 „	700
„ 20 „	500	„ 26 „	750
„ 21 „	540	„ 27 „	800
„ 22 „	580		

Note —The above rates are subject to revision, upwards or downwards, to an extent not exceeding 20 per cent in all, on account of a rise or fall in the cost of living, as compared with the year 1919 A deduction of 4 per cent on this account has already been made A further revision may take place on July 1st, 1927, and every three years thereafter

Further particulars can be obtained on application to the Secretary, Military Department, India Office, Whitehall,-London, S W 1 Letters should be marked " Recruitment for I M S "

ROYAL AIR FORCE MEDICAL SERVICE

The Air Council attach great importance to attracting into the Service the best type of medical man, since on the capacity of the Medical Service depends in a peculiar degree the safety and efficiency of the Air Force The duties of a medical officer in the Air Force include not only the prevention and treatment of those ordinary diseases to which the personnel of any fighting service are liable, but the special study of the mental and physical stresses imposed on the airman in diverse circumstances and climates—a new branch of medicine which still provides considerable scope for research

As promotion to the higher ranks of the Service is by selection from officers who are eligible by reason of length of service, and as a certain proportion of the higher ranks will be reserved for purely scientific as opposed to administrative appointments, it will be seen that there are excellent prospects for the young medical officer who exhibits ability and energy in scientific research, as well as for those who develop a talent for administration

The work to be done, therefore, has a high professional interest which, combined with good rates of pay and allowances, offers a career for medical men which should prove both attractive and interesting The life is one which is certain to appeal to the man of wide outlook who desires opportunities for travel, sport and games, and can find interest and enjoyment in aviation

His duties will, as a matter of course, give him flying experience as a passenger, which is necessary for the proper study of the medical problems of aviation and for gaining first-hand knowledge of the conditions under which his comrades serve

The establishment will consist partly of permanent and partly of short-service officers

An officer will on first entry be granted a short-service commission for a period of three years on the active list (which may be extended to five years at the discretion of the Air Council if the officer so wishes on the recommendation of the Director of Medical Services) and of four years in the Reserve of Air Force Officers Selections for permanent commissions will be made from officers holding short-service commissions, and those who are not selected will be transferred to the Reserve at the expiration of their period of service on the active list

For those entrants who desire it the prospect of obtaining a permanent commission is approximately an even one Experience has so far shown that the officers selected have included the great majority of those desirous of, and suitable for retention in the

ROYAL AIR FORCE MEDICAL SERVICE RATES OF PAY AND ALLOWANCES

Rank	Pay *									Cash allowances in lieu of quarters, rations, and servant if not available in kind (per annum) †						Pay plus allowances per annum

---

* Except for periods of service under Indian administration For such periods officers receive pay and allowances at rates and subject to conditions authorised from time to time by the Government of India

† These allowances are issued only when accommodation fuel and light, rations, and personal attendance are not available in kind. Normally, provision in kind is available for junior officers "Married" rates of allowances are payable only to married officers who have reached the age of 30 A colonial allowance is granted to certain commands abroad

The rates and general scheme of allowances are liable to revision as circumstances may require

Service, owing to the fact that the short-service commission with its gratuity after three or five years is in itself an attraction to many entrants who desire to enlarge their experience and outlook from the point of view of subsequently entering private practice, or who on entry, have not made up their minds to the adoption of a permanent career in the Service and subsequently find that they would prefer to return to civil life

Arrangements exist whereby in the event of a short-service medical officer being approved for a permanent commission and for whom there is no vacancy on the permanent establishment consideration may be given to his transfer to the Royal Army Medical Corps as a permanent officer If transferred his service in the Royal Air Force would count towards increments of pay and towards retired pay in the Royal Army Medical Corps

Medical officers may be allowed to count as service their time spent in resident appointments in civil hospitals under certain well-defined and generous conditions

Officers who have been selected for permanent commissions may be permitted to attend for a period not exceeding nine months a post-graduate course in general medicine and surgery, tropical and preventive medicine and other special subjects Such permission may be granted at any time when the exigencies of the Service permit during the first 16 years of service, and when attending these courses officers will receive full pay and allowances

New entrants into the Royal Air Force Medical Service will be commissioned as Flying Officers (Medical) and will be eligible for promotion to the rank of Flight Lieutenant (Medical) after two years' service Officers selected for permanent commissions will normally be promoted to the rank of Squadron Leader after ten years total service Accelerated promotion may be granted in a limited number of cases to officers who show exceptional ability after the completion of eight years' service Promotion within establishment to the rank of Wing Commander will be by selection at any period after 16 years' total service, and that of Group Captain by selection at any period after 22 years' service

There will be no competitive examination on entry; candidates must be under 28 years of age, be British subjects, the sons of British subjects and of pure European descent, be nominated by the dean of a recognised medical school or teaching hospital, and will be interviewed personally by the Director of Medical Services Royal Air Force, before acceptance. Each candidate must produce —

1 Birth certificate 2 Medical registration certificate 3 A declaration containing the following information (*a*) Age and place of birth (*b*) That he is a British subject, the son of British subjects, and of pure European descent (*c*) That he is ready to engage for general service at home or abroad as required (*d*) The qualifications he is possessed of and what medical or other appointments he has held (if any) (*e*) That he is willing to fly as a passenger whenever called upon to do so

Each candidate will be required, before acceptance, to pass a medical examination to ensure that he labours under no constitutional or mental disease or diseases or weakness, nor any imperfection or disability which may interfere with the efficient discharge of the duties of a medical officer in any climate, in peace or war

On appointment entrants will undergo an initial course of eight weeks during which they will be given instruction in the special medical aspects of aviation, the organisation and administration of the Royal Air Force and the general and special duties to be performed by officers in the Medical Branch

In order to avoid the necessity for further examinations the position of entrants in order of seniority in the Air Force List will be determined at the end of the initial course by a system of *marking and* reports on the actual work done during their instruction

Uniform and Equipment.

Medical officers are required to provide themselves with the uniform, service dress, and mess dress of their rank and with the distinguishing badges of the Royal Air Force Medical Branch The provision of full dress is entirely optional at present An allowance of £50 towards the cost of uniform is made on joining to candidates who have not had previous commissioned service in H M Forces

The emoluments of medical officers of the Royal Air Force are given in outline above The standard rates of pay and retired pay were drawn up on the basis of the high cost of living in 1919, and 20 per cent of each of the standard rates is detachable and subject to alteration either upwards or downwards as the cost of living rises or falls Under this provision the current rates now in force represent a reduction of approximately 5½ per cent on the standard rates. The next revision will take effect from July 1st, 1927. and subsequent revisions will be made at intervals of three years

RETIRED PAY

The minimum period of service qualifying for retirement on retired pay is 20 years Standard rates of retired pay are as follows —

Air Officers

Air Vice-Marshal	£790 to £1010 per annum.
Air Commodore	. £650 , £9[illegible] . .

Retired Pay of Officers below Air Rank

Age on retirement	Standard yearly rate of retired pay	Years of service	Addition for each extra year of service *	Deduction for each deficient year of service *
	£		£	£
40	300	17	15	15
41	337	17	15	15
42	375	18	15	15
43	412	18	15	15
44	450	19	15	15
45	487	19	15	15
46	525	20	15	15
47	562	20	15	15
48	600	21	15	15
49	637	21	15	15
50	675	22	15	15
51	697	22	22	15
52	720	23	22	15
53	742	23	22	15
54	765	24	22	15
55	790	24	22	15

* Limited to five years

The maximum standard rates of retired pay and the compulsory retiring ages for the several ranks are —

Rank	Yearly rate of retired pay	Compulsory retiring age
	£	
Air Vice Marshal	1010	60
Air Commodore	950	57
Group Captain	900	55
Wing Commander	600	51
Squadron Leader	500	48

Gratuities —A permanent officer allowed to retire before having qualified for retired pay may be granted a gratuity provided he has not less than ten years' commissioned service, namely —

£1500 if he has 10 but not less than 15 years commissioned service
£2500 „ 15 or more than 15 „ „ „

Short-service officers will be eligible on passing to the Reserve for gratuities on the following scale £100 for each of the first two complete years of service, £150 for each of the third and fourth complete years, and £200 for the fifth complete year, that is —

For three years' service on the active list	£350
For five „ „ „ „	£700

These gratuities will not be payable to officers granted permanent commissions, but their service on a short-service commission will count towards retired pay

COLONIAL MEDICAL SERVICE

IN the self-governing dominions, Canada, Australia, New Zealand, the Union of South Africa, and Newfoundland, and territories under their control, such as Papua and the Cook Islands, medical appointments are made concerning which information can be obtained from the High Commissioners or Agents-General in London, appointments in Egypt and the Soudan are regulated from the Foreign Office, in Southern Rhodesia the appointments are made by the local Government, but the British South Africa Company, London Wall Buildings, E C, act as their agents in this country, in North Borneo application should be made to the British North Borneo Company, 37, Threadneedle-street, E C, for appointments, and those in Sarawak are in the hands of H H the Rajah Much valuable information will be found in the "Professional Handbook," Part II, issued by the Oversea Settlement Office, 3 and 4, Clement's Inn, Strand, London, W C 2, price 9*d*

As a general rule, each Colony or Protectorate has its own public service distinct from that of every other; and it is usually only the higher officers who are transferred by the Secretary of State from one Colony to another There are three exceptions to this rule (*a*) The West African Medical Staff, which serves Nigeria, the Gold Coast, Sierra Leone, and the Gambia, is one service. (*b*) The East African Medical Service, which serves Kenya, Uganda, Zanzibar, Nyasaland, Somaliland, and the Tanganyika Territory is one service (*c*) In practice the medical services of the Straits Settlements and the Malay States may be regarded as one, as the officers may be and frequently are transferred from the Colony to the States or vice versa

The Colonies, Protectorates, and Mandated Territories to which medical officers are appointed by the Secretary of State for the Colonies are (*a*) the West African—viz, Nigeria, the Gold Coast, Sierra Leone, and the Gambia; (*b*) the East African—viz, the Kenya Colony and Protectorate, the Uganda, Nyasaland, Somaliland, and Zanzibar Protectorates, the Tanganyika Territory, and Northern Rhodesia, (*c*) the Eastern—viz, Ceylon, the Straits Settlements and Malay States, Hong-Kong, Mauritius, and Seychelles, (*d*) the West Indian—viz, British Guiana, Jamaica, Trinidad, the Windward Islands, the Leeward Islands, Barbados, British Honduras, and the Bahamas, (*e*) Fiji and the Western Pacific, Cyprus, Gibraltar, St Helena, Bermuda, and the Falkland Islands, and (*f*) Palestine

In Ceylon, Mauritius, Jamaica, Barbados, the Bahamas, and Bermuda vacancies are practically always filled locally by the appointment of qualified native candidates, or—in the case of some of the higher posts—by transfer from other Colonies Appointments in Malta are all filled locally Vacancies occur most regularly and frequently in the West African Medical Staff, the East African Medical Service, and the Straits Settlements and Malay States

All applicants for medical appointments in the gift of the Secretary of State for the Colonies should be between the ages of 23 and 35 [1] and must be doubly qualified, preference will be given to those who have held hospital appointments as house physicians and house surgeons; testimonials to character and professional competence will be required, and every officer before being definitely appointed will be medically examined by one of the consulting physicians of the Colonial Office Sir William Prout, C M G, O B E, and Dr A E Horn, C M G, 79, Harley-street, London, W 1, Sir J Hawtrey Benson, 57, Fitzwilliam-square, Dublin, Dr Foster Coates, 9, Shaftesbury-square, Belfast, Lieut -Colonel Glen Liston, C I E, I M S, 33, Comely Bank, Edinburgh, and Dr R H Kennan, 2, St James's-road, Liverpool Applications for such appointments must be addressed to the Private Secretary (Appointments), Colonial Office, 38, Old Queen street, S W 1

EAST AFRICAN MEDICAL SERVICE

The Medical staffs of the Kenya Colony and Protectorate, the Uganda, Nyasaland, Somaliland, and Zanzibar Protectorates, and the Tanganyika Territory form one service, the members of which are liable to be posted to any of the Dependencies as the exigencies of the service may require The preferences of individual officers are, however, taken into consideration as far as possible

Selected candidates are appointed as medical officers on probation in the first instance for two years, at the end of which period their appointments are made permanent if their service has been satisfactory Unless the Secretary of State directs to the contrary, they are required to attend a course of instruction at the London or Liverpool School of Tropical Medicine before taking up their appointments If such a course is not taken before proceeding to East Africa, they are required to take it during their first leave of absence Medical officers (but not sanitation officers) are permitted to take private practice at some stations, on the understanding that they give precedence to their official duties It must be understood that additions to their income from this source are not likely to be substantial, and that the privilege is liable to withdrawal at any time

---

[1] In the case of East Africa preference will be given to candidates who are over 25 years of age In the case of Fiji and the Western Pacific, preference will be given to candidates who are under 30

Salaries and allowances are issued locally in respect of resident service at a fixed rate of 20 shillings to the pound sterling

Officers are provided with quarters free of rent or the Government may provide temporary accommodation, or an allowance in lieu of quarters calculated at 15 per cent of the initial salary of an officer's appointment may be paid The salary of a medical or sanitation officer in Kenya Uganda the Tanganyika Territory, or Zanzibar is £600 per annum, rising by annual increments of £30 to £840 and thence by increments of £40 to £920, subject to an efficiency bar at £840 Senior medical officers and senior sanitation officers in those Dependencies are paid on the scale £1000 by annual increments of £50 to £1100 The application of these scales to Nyasaland and Somaliland is under consideration, at present the scale for medical officers in those Dependencies is £600 by £25 to £900, with efficiency bars at £700 and £800 Officers who possess the Diploma in Public Health on entering or who acquire it while in the Service receive two special increments in the scale

Officers of the East African Medical Service are permitted to retire with gratuity, if they wish instead of waiting to retire on pension as follows (*a*) After nine years' service, of which at least six must have been spent in East Africa, £1000, (*b*) after 12 years' service, of which at least eight must have been spent in East Africa, £1250 If an officer elects to retire with gratuity, he thereby foregoes all claim to pension

The grades and salaries (apart from ordinary medical and sanitation officers) in the medical departments are as follows —

Kenya—Director of Medical and Sanitary Services, £1500, Deputy Director of Medical Service, £1200, Deputy Director of Sanitary Service, £1200, Surgical Specialist, £1200, Director of Laboratory, £1200

Uganda—As Kenya

Tanganyika Territory—As Kenya, except that there is no surgical specialist

Nyasaland—Director of Medical and Sanitary Services, £1000, Senior Medical Officer and Senior Sanitation Officer, £800 by £25 to £900

Zanzibar—Director of Medical and Sanitary Services, £1400, Deputy Director of Sanitary Service, £1200

Somaliland—Principal Medical Officer, £900 by £50 to £1000

Sanitation officers are selected from the ranks of medical officers as occasion arises

ASIA

Straits Settlements and Federated Malay States—European medical officers are appointed on the following scale of salaries · $440 per mensem, rising to $480 per mensem during three years' probation; then, if they are placed on the pensionable establishment, rising to $500 per mensem, and thence by annual increments of $25 per mensem to $800 per mensem, with a strict efficiency bar at $600 per mensem This scale of salaries has been fixed on the supposition that medical officers join the service at about the age of 27. Above the concluding figure of $800 per mensem there are certain higher appointments as follows Principal Civil Medical Officer, Straits Settlements, and Principal Medical Officer, Federated Malay States, $1200 per mensem Class A seven posts at $1050 per mensem Class B nine posts at $850, rising by $30 to $1000 per mensem

The following temporary allowances are at present paid to all officers recruited from Europe in the Government Services of the Straits Settlements and Federated Malay States unmarried officers, 10 per cent of salary, married officers, 20 per cent of salary. Private practice by Government medical officers is not allowed They may, however, do, and receive fees for, consultative work, if approved by the Government Information about general conditions in Malaya is obtainable from the Malay States Information Agency, 88, Cannon-street, E.C. 4

Seychelles—The chief medical officer receives Rs 7000 and Rs 300 in fees There are three assistant Government medical officers, two receiving Rs 6500, with free quarters or an allowance of Rs 500 per annum in lieu the other Rs 6000 One assistant is provided with free quarters in the New Hospital

Hong-Kong—The present establishment of the medical department is principal civil medical officer, £1000–£50–£1200: eight medical officers, £600–£25–£1000, three port health officers, £600–£25–£1000, bacteriologist £700–£25–£1000. two health officers, £600–£25–£1000 are also attached to the Sanitary Department. A temporary allowance on a scale varying with the sterling exchange value of the dollar is at present payable. Salaries are converted locally at the rate of 2*s* = $1 Free quarters are not provided, but in certain instances a rent allowance is paid by the Government

AMERICA

British Guiana—There are the following posts in the medical service of the Colony. one surgeon-general £1000–£1200 per annum, with consulting practice, one medical officer of health £900, one bacteriologist £450–£700 (increment £25) with £50 allowance in lieu of fees; 34 medical officers at £500–£25–£700 Some of the senior posts also carry duty allowances (varying from £50 to £300 per annum) and quarters All the junior appointments in which private practice is not allowed carry duty allowances Private practice is allowed in certain cases

Trinidad and Tobago—In Trinidad and Tobago there are over 40 appointments On appointment Government medical officers who are provided with free unfurnished quarters, receive salary at the rate of £400 per annum with annual increments of £25 accruing from the date of first appointment as supernumerary medical officers until reaching the maximum of £600 An officer appointed to a district receives, in addition to his salary. a travelling allowance varying from £100 per annum in a normal district to £150 per annum and is allowed private practice, the value of which is estimated at from £50 to £800 per annum Officers employed in institution work receive allowances in lieu of private practice varying from £50 (and furnished quarters) to £300. Medical officers having completed 10 years' resident service are pensionable at the age of 55

Windward Islands (Grenada, St Lucia St Vincent) There are over 25 appointments The chief medical and health officer, Grenada receives £600–£700 The chief medical officer, St Lucia, receives £600–£700 plus forage and subsistence allowances, the post is pensionable, but private practice is *not* allowed except as a consultant Most of the remaining appointments are district appointments with the right to private practice attached, the salaries paid by Government vary from £400–£500, and with allowances in certain cases The Governor has the power to transfer a medical officer from one island to another Appointments are pensionable

Leeward Islands (Antigua St Christopher and Nevis Dominica Montserrat Virgin Islands)—There are 20 appointments with salaries varying from £375 to £400 of the same nature as in the Windward Islands and pensionable An officer when first sent out is not appointed to a particular island but to the service of the Leeward Islands, with a salary varying from £312 to £400, according to station, and the Governor decides as to the district which is to be allotted to him He is liable to be transferred at the Governor's discretion to any medical district in the Leeward Islands, and in certain districts may be required to perform magisterial duties The medical officers receive fees for successful vaccinations post-mortem examinations, evidence at courts of justice, certificates of lunacy, and, in the larger islands, for burial certificates They are also as a rule allowed private practice The chief medical officer, St Kitts receives £700–£25–£750 without private practice

Antigua—Medical Superintendent Holberton Hospital and Chief Medical Officer is in receipt of a salary of £600, plus £50 as Chief Medical Officer and travelling allowance of £25 Fees average £100.

British Honduras —There are seven medical appointments (besides the principal post of colonial surgeon) of which six are at a salary of $2430 per annum with increments of $120 to $3150 Unless they already possess a diploma of public health, medical officers are liable to be required, before they join the colony, to undergo a course of instruction at a laboratory of public health or analogous institution The salary of the Principal Medical Officer is $4008, with one increment of $120 to $4128 The value of the dollar is approximately the same as that of the United States

OTHER OVERSEAS APPOINTMENTS

Fiji and the Western Pacific —In Fiji the Government medical officers receive a salary of £400, rising by annual increments of £25 to £600, with partly furnished quarters, or a house allowance of £50 In some districts a medical officer is also a district commissioner, with an additional allowance of £150 They are allowed private practice, on the understanding that their official duties are not neglected Private practice, however, cannot be guaranteed, and in most districts it is very small in amount Where no private practice exists, a duty allowance of £50 is granted They are required either to take charge of hospitals or of districts, at the discretion of the authorities The posts are pensionable

In addition to a chief medical officer (£800 a year, rising to £1000), a medical officer of health, Suva (£750–£900, not subject to bonus addition), a medical superintendent, Colonial Hospital (£700–£750, inclusive of allowance as officer in charge of the Medical School), and a medical superintendent, Makogai Leper Asylum (£600 rising to £800), there are in Fiji 12 medical officers, five of whom are also district commissioners The salaries in Fiji are subject to temporary increases, the rate of bonus at the present time being 15 per cent of the salary with the addition of £22 10*s*

The staff in the British Solomon Islands Protectorate consists of one senior medical officer (£700 and hospital fees) and two medical officers (£550 rising to £650) A local allowance at the rate of £50 per annum is also paid in respect of actual resident service in the Protectorate In the Gilbert and Ellice Islands Colony there is one medical officer in charge (£650 rising to £750) Officers may be transferred from Fiji to the Western Pacific and vice versa at the discretion of the Secretary of State

Cyprus —There is a chief medical officer paid at the rate of £750, rising by annual increments of £25 to £900, and three district medical officers paid at the rate of £500 a year, rising by annual increments of £20 to £600 a year, all enjoying private practice (except the chief medical officer, who is allowed consulting practice only) and receiving 2*s* per diem forage allowance There is also a medical officer of health on £600, rising by £20 increments to £720 without private practice; these are the only medical appointments open to English candidates

Gibraltar —There is a surgeon of the Colonial Hospital receiving £750, and private practice There are also two assistant surgeons with a salary of £720 per annum, who are allowed private consulting practice only Free quarters, unfurnished, are provided for all three officers

St Helena —The colonial surgeon at present receives £550 per annum, £20 fees as health officer, and £30 horse allowance Private practice is allowed The assistant colonial surgeon at present receives £500 a year and a horse allowance, and is allowed a share of the private practice For contracts and appointments the colonial surgeon also receives about £250 a year and the assistant about £150

Falkland Islands —There are two appointments The colonial surgeon is paid at the rate of £600 per annum, with free furnished quarters The assistant colonial surgeon is paid at the rate of £500 per annum, with an allowance of £50 per annum in lieu of quarters. Private practice is shared between the colonial surgeon and the assistant colonial surgeon. The office of colonial surgeon is pensionable

Palestine [2]—The grades and salaries of superior appointments in the Department of Health are. Director, £E1100–50–1400, plus £E100 expatriation allowance Deputy director, senior medical officer (laboratory section), and senior medical officer (Jerusalem-Jaffa district) £E800–50–1100 plus £E100 expatriation allowance Chemical analyst, three senior medical officers, and medical officer (Jerusalem-Jaffa district) £E550–25–750 plus £E50 expatriation allowance The remainder of the staff is recruited locally The salaries of the two highest grades will be reduced as vacancies occur

LEAVE AND PENSIONS

Leave and Passages —Leave of absence in East Africa on full salary is granted in the normal case after a tour of residential service (of not less than 20 and not usually more than 30 months) to an amount of six days for each completed month of residence (or three days when for any reason the officer is not returning to East Africa) exclusive of the periods of the voyages to and fro, for which full pay is also given Officers serving in certain stations in Kenya and Nyasaland, are allowed five (or two and a half) days' leave in respect of each month of service instead of six (or three) days' leave respectively In Somaliland special leave regulations exist which provide for an officer taking leave after a shorter tour of service than in other parts of East Africa Free first-class passages are provided for the officer on first appointment and on leave, and in certain cases assistance towards family passages is given

In the Malay Peninsula two months' leave of absence with full salary may be granted in respect of each year's service, and this leave may be accumulated up to a maximum of eight months Additional leave on half-pay may be granted on special grounds Up to the end of 1928 free passages are granted on first appointment and on leave, and free passages on first appointment or transfer are granted permanently for officers with salary under £800

In other Colonies outside Tropical Africa, subject to the necessities of the service, leave of absence on half salary may be granted after a period of three years' resident service without any special grounds It may be given before the expiration of that period in case of serious indisposition, or of urgent private affairs In the absence of special grounds, the leave must not exceed one-sixth of the officer's resident service, on special grounds it may exceed that period by six months In addition to the above, vacation leave on full pay may be granted, if no inconvenience or expense is caused thereby, not exceeding three months [3] in any two years In British Guiana assisted passages are granted to officers proceeding on leave and officers are allowed to accumulate full-pay leave at the rate of six weeks for each year's service up to six months, and no leave of absence may (except in very special circumstances) exceed six months in all unless the officer has served for five years or more without leave, in which case two months on half-pay may be taken in addition to six months' full-pay leave

On first appointment an officer will, except in the case of a few Colonies possessing Representative Assemblies, be provided by the Crown Agents for the Colonies with free passages to the Colony for himself and his wife and children, if any, not exceeding four persons besides himself The officer so appointed will be required to execute an agreement binding him to repay the cost of the passage or passages so obtained in the event of his leaving the Government service within three years An officer taking leave out of the Colony has in most cases to provide his own passages

---

[2] £1 Egyptian (of 100 piastres) is equivalent to £1 0*s* 6*d* sterling

[3] Or, in the case of Fiji and the Western Pacific and the Falkland Islands 4½ months in any three years

Pensions—East Africa—Officers on the pensionable establishment retire on attaining the age of 50 years or after 20 years' East African service, whichever is earlier; but they may be retained in the service, with their own consent, for such further period as the Government may recommend Earlier retirement in the event of ill-health is also provided for. Pension is computed at one-sixtieth of pensionable emoluments—i e, salary and value of free quarters[*]—at the time of retirement, two years' service being reckoned as three years for this purpose, subject to an average of emoluments for the last two years before retirement instead of the actual emoluments at the time of retirement being taken as the basis for calculation in certain circumstances

Other Colonies—In most of the other Colonies an officer holding a pensionable appointment may be allowed in the case of ill-health to retire on a pension after ten full years' resident service, otherwise he must have attained the age of 55 For ten full years' resident service fifteen-sixtieths of the average annual salary of the retiring officer's fixed appointments for three years prior to retirement may be awarded, to which one-sixtieth may be added for each additional year's service; but no addition will be made in respect of any service beyond 35 years For pension purposes absence on vacation leave counts as full service, and leave on half-pay as half service In a few cases the retiring age is 60 and the pension after ten years' service is ten-sixtieths instead of fifteen In the Straits Settlements and Malay States an officer may, with the consent of Government, retire at age 50 Pensions are calculated on a basis of length of service in months instead of years.

WEST AFRICAN MEDICAL STAFF

Applicants for appointment as medical officers in the West African Medical Staff (the higher grades will usually be filled by promotion from the lower) must be British subjects of European parentage and between 23 and 35 years of age, preference is given to candidates who are over 25 years of age Applicants must possess a complete double qualification, and must be on the Medical Register Passages for wives and children are not provided by the Government, and houses for the wives of junior medical officers are rarely available Officers are not allowed to take their wives and young children out with them until they have acquired experience of the local conditions and have obtained the sanction of the Governor

Candidates whom it is proposed to select for appointment will have to be medically examined by one of the medical advisers of the Colonial Office (or, in the case of those residing in a Colony, by a medical officer appointed by the Colonial Government), and no appointment will be made unless the candidate is declared to be physically fit for service in West Africa Candidates are allowed to express a preference for any particular Colony or Protectorate, and their wishes in this respect will be borne in mind and met as far as possible, but they are liable to be posted in the first instance, or transferred afterwards if necessary to any other West African Colony or Protectorate at the discretion of the Secretary of State Candidates who wish to be posted to the Northern Provinces of Nigeria should be able to ride Transfers from one Colony or Protectorate to another will be made as seldom as possible Candidates should on no account apply for, or accept, a West African appointment in the expectation of ultimately being transferred

Those transferred to pensionable Crown appointments elsewhere than in West Africa do not forfeit their claim to pension in respect of their West African service on final retirement, provided that they have been members of the staff for at least 12 months Every officer selected for appointment is required to have himself revaccinated before proceeding to West Africa, unless one of the medical advisers of the Colonial Office certifies that this is unnecessary

Instruction in Tropical Medicine—Every candidate selected for appointment will, unless the Secretary of State decides otherwise, be required to undergo a course of instruction for five to six months, either at the London School of Hygiene and Tropical Medicine Endsleigh-gardens, N W, 1, or at the Liverpool School of Tropical Medicine, University, Liverpool The cost of tuition will be borne by the Government, but candidates must make their own arrangements for board and lodging; an allowance of £3 a week will be paid to them monthly in arrear for this purpose A daily allowance of 5*s* (but no salary) will be paid to each candidate monthly in arrear during the course, and may be continued up to the date of embarkation. He will be bound to refund (1) if he declines to accept an appointment in any of the Colonies or Protectorates for which he may be selected, (2) if he fails to obtain a certificate in regard to progress and efficiency, or (3) if he relinquishes the Service for any other reason than mental or physical infirmity, or is removed for misconduct, within three years of his arrival in West Africa

If at the end of the session there exists no vacancy in the Staff to which a candidate can be appointed, he will be placed in a Reserve and granted an allowance at the rate of £200 a year until the occurrence of a vacancy

Leave of Absence—European officers in West Africa may be granted vacation leave on full salary not exceeding in all one week's leave in the United Kingdom for every completed calendar month of total residential service in West Africa, plus the time necessarily taken on the journey to the United Kingdom, and, if the officer is returning to West Africa for further service, the time necessarily taken on the journey from the United Kingdom to the Colony Vacation leave may be granted without any special grounds after 18 consecutive calendar months of residential service in West Africa An officer will not be required to serve a tour of more than 24 consecutive calendar months' residential service except in special circumstances, and the Governor may grant vacation leave to any officer at any time after he has completed 12 consecutive calendar months' residential service Vacation leave on full salary may also be granted to an officer if he is invalided from West Africa after less than 12 consecutive calendar months' residential service, and sick leave on full salary may be granted for any period not exceeding six calendar months

Appointments and Salaries.—The Medical Services of the West African Colonies and Protectorates—namely, the Gambia, Sierra Leone, the Gold Coast (including Ashanti and the Northern Territories), and Nigeria (Southern and Northern Provinces)—form one service under the name of the West African Medical Staff All the medical officers for the service are selected by the Secretary of State for the Colonies, and are on one list for employment and promotion The grades and emoluments of the Staff are at present as follows —

The Director of the Medical and Sanitary Service, Nigeria, receives a salary of £1800 a year, with a duty allowance at the rate of £360 a year The Director of Medical and Sanitary Service in the Gold Coast receives a salary of £1600 a year, with a duty allowance at the rate of £320 a year The Director of Medical and Sanitary Service in Sierra Leone receives a salary of £1400 a year, with a duty allowance at the rate of £280 a year The Deputy Director of Medical and Sanitary Service, Nigeria, and the Deputy Director of Sanitary Service, Nigeria, receive salaries of £1500 a year, with duty allowances at the rate of £300 a year The Deputy Director of Medical and Sanitary Service, Gold Coast, receives a salary of £1400 a year, with duty allowance at the rate of £280 a year Assistant Directors Medical Service There are nine appointments on this grade, six in Nigeria two in the Gold Coast and one in Sierra Leone The salary is at the rate of £1300 a year, with duty allowance at the rate of £260 a year. The Assistant Director of Sanitary Service, Nigeria, the Deputy Director of Sanitary Service in the Gold Coast and the Deputy Director of Sanitary Service in Sierra Leone receive salary at the rate of £1300 a year, with duty allowance at the rate of £260 a year Specialists The number of these appointments is not fixed, officers of outstanding professional merit being eligible for appointment a salary of £600, plus £50 as Chief Medical Officer and travelling allowance of £25 Fees average £100

---

[*] The value of free quarters for pension purposes is taken as 15 per cent. of the minimum salary of the grade in which an officer is serving at the time of retirement

British Honduras—There are seven medical appointments (besides the principal post of colonial surgeon) of which six are at a salary of $2430 per annum with increments of $120 to $3150 Unless they already possess a diploma of public health, medical officers are liable to be required, before they join the colony, to undergo a course of instruction at a laboratory of public health or analogous institution The salary of the Principal Medical Officer is $4008, with one increment of $120 to $4128 The value of the dollar is approximately the same as that of the United States

OTHER OVERSEAS APPOINTMENTS

Fiji and the Western Pacific—In Fiji the Government medical officers receive a salary of £400, rising by annual increments of £25 to £600, with partly furnished quarters, or a house allowance of £50. In some districts a medical officer is also a district commissioner, with an additional allowance of £150 They are allowed private practice, on the understanding that their official duties are not neglected Private practice, however, cannot be guaranteed, and in most districts it is very small in amount Where no private practice exists, a duty allowance of £50 is granted They are required either to take charge of hospitals or of districts, at the discretion of the authorities The posts are pensionable

In addition to a chief medical officer (£800 a year, rising to £1000), a medical officer of health, Suva (£750–£900, not subject to bonus addition), a medical superintendent, Colonial Hospital (£700–£750, inclusive of allowance as officer in charge of the Medical School), and a medical superintendent, Makogai Leper Asylum (£600 rising to £800), there are in Fiji 12 medical officers, five of whom are also district commissioners The salaries in Fiji are subject to temporary increases, the rate of bonus at the present time being 15 per cent of the salary with the addition of £22 10*s*

The staff in the British Solomon Islands Protectorate consists of one senior medical officer (£700 and hospital fees) and two medical officers (£550 rising to £650) A local allowance at the rate of £50 per annum is also paid in respect of actual resident service in the Protectorate In the Gilbert and Ellice Islands Colony there is one medical officer in charge (£650 rising to £750) Officers may be transferred from Fiji to the Western Pacific and vice versa at the discretion of the Secretary of State

Cyprus—There is a chief medical officer paid at the rate of £750, rising by annual increments of £25 to £900, and three district medical officers paid at the rate of £500 a year, rising by annual increments of £20 to £600 a year, all enjoying private practice (except the chief medical officer, who is allowed consulting practice only) and receiving 2*s*. per diem forage allowance There is also a medical officer of health on £600, rising by £20 increments to £720 without private practice, these are the only medical appointments open to English candidates

Gibraltar—There is a surgeon of the Colonial Hospital receiving £750, and private practice. There are also two assistant surgeons with a salary of £720 per annum, who are allowed private consulting practice only. Free quarters, unfurnished, are provided for all three officers

St Helena—The colonial surgeon at present receives £550 per annum, £20 fees as health officer, and £30 horse allowance Private practice is allowed The assistant colonial surgeon at present receives £500 a year and a horse allowance, and is allowed a share of the private practice For contracts and appointments the colonial surgeon also receives about £250 a year and the assistant about £150

Falkland Islands—There are two appointments The colonial surgeon is paid at the rate of £600 per annum, with free furnished quarters The assistant colonial surgeon is paid at the rate of £500 per annum, with an allowance of £50 per annum in lieu of quarters Private practice is shared between the colonial surgeon and the assistant colonial surgeon The office of colonial surgeon is pensionable

Palestine [1]—The grades and salaries of superior appointments in the Department of Health are. Director, £E1100–50–1400, plus £E100 expatriation allowance Deputy director, senior medical officer (laboratory section), and senior medical officer (Jerusalem-Jaffa district) £E800–50–1100 plus £E100 expatriation allowance Chemical analyst, three senior medical officers, and medical officer (Jerusalem-Jaffa district) £E550–25–750 plus £E50 expatriation allowance The remainder of the staff is recruited locally. The salaries of the two highest grades will be reduced as vacancies occur

LEAVE AND PENSIONS

Leave and Passages—Leave of absence in East Africa on full salary is granted in the normal case after a tour of residential service (of not less than 20 and not usually more than 30 months) to an amount of six days for each completed month of residence (or three days when for any reason the officer is not returning to East Africa) exclusive of the periods of the voyages to and fro, for which full pay is also given Officers serving in certain stations in Kenya and Nyasaland, are allowed five (or two and a half) days' leave in respect of each month of service instead of six (or three) days' leave respectively In Somaliland special leave regulations exist which provide for an officer taking leave after a shorter tour of service than in other parts of East Africa Free first-class passages are provided for the officer on first appointment and on leave, and in certain cases assistance towards family passages is given

In the Malay Peninsula two months' leave of absence with full salary may be granted in respect of each year's service, and this leave may be accumulated up to a maximum of eight months Additional leave on half-pay may be granted on special grounds Up to the end of 1928 free passages are granted on first appointment and on leave, and free passages on first appointment or transfer are granted permanently for officers with salary under £800

In other Colonies outside Tropical Africa, subject to the necessities of the service, leave of absence on half salary may be granted after a period of three years' resident service without any special grounds It may be given before the expiration of that period in case of serious indisposition, or of urgent private affairs In the absence of special grounds, the leave must not exceed one-sixth of the officer's resident service, on special grounds it may exceed that period by six months In addition to the above, vacation leave on full pay may be granted, if no inconvenience or expense is caused thereby, not exceeding three months [2] in any two years In British Guiana assisted passages are granted to officers proceeding on leave and officers are allowed to accumulate full-pay leave at the rate of six weeks for each year's service up to six months, and no leave of absence may (except in very special circumstances) exceed six months in all unless the officer has served for five years or more without leave, in which case two months on half-pay may be taken in addition to six months' full-pay leave

On first appointment an officer will, except in the case of a few Colonies possessing Representative Assemblies, be provided by the Crown Agents for the Colonies with free passages to the Colony for himself and his wife and children, if any, not exceeding four persons besides himself The officer so appointed will be required to execute an agreement binding him to repay the cost of the passage or passages so obtained in the event of his leaving the Government service within three years An officer taking leave out of the Colony has in most cases to provide his own passages

---

[1] £1 Egyptian (of 100 piastres) is equivalent to £1 0*s* 6*d*. sterling

[2] Or, in the case of Fiji and the Western Pacific and the Falkland Islands 4½ months in any three years

SPECIAL DIPLOMAS

DIPLOMA IN TROPICAL MEDICINE

ALTHOUGH a qualification in tropical medicine has not been made registrable by statute, a diploma is regarded as indispensable for appointments in the Colonial Medical Service and similar positions abroad Systematic instruction for these diplomas is given at the Incorporated Liverpool School of Tropical Medicine (founded in 1898) and at the London School of Hygiene and Tropical Medicine 23, Endsleigh-gardens, Euston-road, N W 1

University of Cambridge—The examination for the Diploma in Tropical Medicine and Hygiene is divided into two parts Part I is held in Cambridge in April and Part II in July in London Candidates for Part I are examined under the same regulations and in the same subjects as candidates for the Diploma in Public Health, but any qualification in medicine or surgery recognised by the proper authority of any country outside the British Dominions may be recognised The subjects for Part II are Medicine, Surgery, and Hygiene in their relation to Tropical Disease

The examination will be partly in writing, partly oral, and partly practical or clinical (the clinical part will be conducted at a hospital for tropical diseases, at which cases will be submitted for diagnosis and comment) Every candidate who passes the examination to the satisfaction of the examiners will receive from the University a diploma (D T M & H) testifying to his knowledge and skill in tropical medicine and hygiene

The fee for each part of the examination is £10 10*s* Further information respecting the courses of study and examinations may be obtained from Mr J E Purvis Public Health Chemical Laboratory, Cambridge

University of London—The M D degree may be taken in tropical medicine at an examination held twice annually, for which a thesis may be submitted

University of Liverpool—The University grants a Diploma in Tropical Medicine At the end of each full course an examination is held by the University for its Diploma of Tropical Medicine (D T.M), which is open only to those who have been through the course of instruction of the school The subjects of examination are (*a*) Tropical Pathology, Parasitology and Entomology; (*b*) Tropical and Applied Bacteriology, (*c*) Tropical Hygiene and Sanitation; (*d*) Tropical Medicine, including Ætiology, Symptoms, Diagnosis, and Treatment of Tropical Diseases The advanced course consists entirely of Practical and Clinical Laboratory Work, given at the laboratory at the University The fee for the full course of instruction is £15 15*s* Applications should be made to the Dean of the Medical Faculty, University of Liverpool

A diploma in Tropical Hygiene (D T H) has recently been established The subjects of examination are bacteriology), chemistry (including meteorology and climatology), entomology, protozoology, and helminthology; tropical sanitation (including sanitary engineering), practical sanitation Fee for the course £15 15*s* Two University Fellowships of £100 a year each are open to students of the school, amongst others Accommodation for research work is to be had at the University Laboratory The Mary Kingsley Medal is awarded by the school for distinguished work in connexion with Tropical Medicine.

Conjoint Board R C.P Lond, R C S Eng—The diploma of D T M & H Eng is awarded on the results of an examination held twice yearly, in February and July Candidates must possess a registrable qualification and produce evidence of having attended (1) practical instruction in pathology, protozoology, helminthology, entomology, bacteriology, and hygiene in relation to tropical medicine in a recognised institution during not less than five months (2) clinical practice of a recognised hospital for the same period Conditions of study may be modified in the case of candidates of special experience Fee for admission to the examination, £9 9*s*, 14 days' notice of entry to the Secretary, Examination Hall, Queen-square, London, W.C 1.

DIPLOMA IN PSYCHOLOGICAL MEDICINE

The Universities of Cambridge London Durham, Leeds Manchester and Edinburgh, Trinity College, Dublin and the Conjoint Board of the R C P Lond and R C S Eng now grant diplomas in psychological medicine under conditions that are fairly comparable in the standard of the tests and in the duration of the courses the details on these points can be obtained from the various examination bodies

In London, courses of instruction for the Diploma in Psychological Medicine are given at the Maudsley Hospital, Denmark Hill, which has recently been definitely recognised as a school of the University of London The course consists of two parts and is adapted for the diploma of the Conjoint Board the University of London, or the University of Cambridge The fee for the whole course (Parts I. and II) is 15 guineas, or for either part separately 10 guineas

Appointments as clinical assistants are obtainable at the Maudsley Hospital The holding of such appointments for varying periods satisfies the requirements of the different examining bodies in respect of practical study of mental disorders The appointments and other facilities for clinical experience are open to qualified medical practitioners apart from the courses of instruction Inquiries as to lectures should be addressed to the Director of the Pathological Laboratory, Maudsley Hospital. Denmark Hill S E 5; and as to clinical facilities, to the Medical Superintendent at the same address

A course of lectures and practical instruction for the Diploma in Psychological Medicine. granted by the various universities and the Conjoint Board is held at Bethlem Royal Hospital London. S E, twice annually during the spring and autumn The fee for the full course is 15 guineas. Part A or Part B, however, may be taken separately at a fee of 10 guineas per part In addition to the above clinical instruction in Psychological Medicine is given at Bethlem Royal Hospital every morning (except Wednesdays) at 11 A M The fee for students is 3 guineas for a period of three months' attendance and for post-graduates a fee of 5 guineas for a like period A reduction is made to those who attend the Diploma Course House physicians are appointed at Bethlem Royal Hospital for a term of six months, which may be extended These appointments are made on May 1st and Nov 1st in each year and the vacancies are advertised in the medical papers. Apartments complete board, attendance and laundry are provided and also a salary at the rate of £100 per annum Clinical assistants are often appointed from time to time for periods of three months or longer. These are non-salaried and non-resident posts but partial board is provided The Physician-Superintendent, Bethlem Royal Hospital, will supply further particulars

In Ireland a post-graduate diploma is conferred on registered medical practitioners who subsequent to registration, have held for at least 12 months a resident medical appointment in a recognised hospital for the treatment of Mental Diseases or have held such an appointment for at least six months and have also attended daily for six months on the practice of an approved institution as aforesaid in which clinical instruction is given. they must also have attended certain courses of instruction and have passed a special examination

The salary is at the rate of £1300 a year, with duty allowance at the rate of £260 a year After five years' approved service as such, the specialist officer is eligible to receive a salary at the rate of £1400 a year, with duty allowance at the rate of £280 a year There are at present five officers appointed specialists in Nigeria and four in the Gold Coast Senior Medical Officer There are twenty appointments of this grade, with salary at the rate of £1000 a year, rising by annual increments of £50 to £1150 a year, and seniority allowance at the rate of £100 a year The Senior Medical Officer, Gambia, is allowed "staff pay" of £150 a year, in addition to duty allowance, but he is debarred from private practice Senior Sanitary Officer There are six appointments of this grade, with salary at the rate of £1050 a year, rising by annual increments of £50 to £1200 a year, and a duty allowance at the rate of £210 a year Medical Officer The salary attached to this grade is at the rate of £660 a year, rising by annual increments of £30 to £720 a year Then, if confirmed in the appointment, £720 a year, rising by annual increments of £40 to £960, with seniority allowance at the rate of £72 a year. Before passing £800, medical officers are required to take a special course of study for three months If they obtain satisfactory certificates at the end of the course they draw their further increments up to £960 a year

A medical officer who has served for three years on the maximum salary of this scale (£960) without obtaining promotion is eligible, if recommended by the Governor, to be placed on the scale £1000–£50–£1150, with £100 seniority allowance (as for Senior Medical Officers)

Special Appointments —The Director of the Medical Research Institute, Lagos, and the Director of Research, Accra, receive a salary of £1300 a year, with a duty allowance of £260 a year, rising after five years' approved service to a salary at the rate of £1400 a year and duty allowance at the rate of £280 a year Salary at the rate of £800 a year, rising by annual increments of £40 to £960 a year is attached to about 17 posts (those of assistant at the Medical Research Institute, Lagos, and medical officers of health at various places), irrespective of the seniority of the officer holding the appointment In addition to the seniority allowance (£72 a year), staff pay at the rate of £150 a year is also attached to these posts; and the holder of the appointment draws half of the staff pay during leave of absence, the remainder being drawn by his locum tenens The holders of these appointments are not allowed private practice Duty allowances, seniority allowance, and staff pay are not pensionable emoluments

Increments —Increments to salaries are payable only when the service of an officer during the period of employment qualifying for increment is approved

Payment of Salaries —Information as to the payment of officers' salaries or of monthly remittances to persons in England may be obtained from the Crown Agents for the Colonies, 4, Millbank, S W 1 All allowances are paid locally

All officers of the staff, except directors, deputy directors, assistant directors, senior sanitary officers, and a few other officers holding special appointments, are at present allowed to take private practice, provided that it does not interfere with the faithful and efficient performance of their official duties, but it is within the power of the Governor to withdraw or suspend the privilege in such places and for such periods as he may consider desirable Private practice does not exist at the majority of stations, and no guarantee can be given that an officer will be posted to a station in which he will be able to practise privately As a general rule, and subject to the exigencies of the service, stations where there is private practice are allocated to senior members of the Staff

Pensions and Gratuities —Pensions and gratuities on retirement are granted in accordance with the law and regulations of each individual Colony

Fuller information can be obtained from the Private Secretary, Colonial Office 38, Old Queen-street, London, S W 1

SUDAN MEDICAL SERVICE

This service is responsible for carrying out civil medical and public health duties in the Sudan The staff consists of —(*a*) A Director—pay £1500–£1800 (*b*) A Senior Physician and a Senior Surgeon to the Khartoum and Omdurman Civil Hospitals—pay £1200–£1750 (*c*) An Assistant Director and Medical Officer of Health, Khartoum Province—pay £1200 (This post is of a temporary nature and the terms and nature of the duties are subject to alteration) (*d*) Twenty-four "Senior Medical Inspectors" and "Medical Inspectors" who are all British The pay of the Inspectors commences at £720, and rises, subject to the recommendation of the Director, by five biennial increases to £1080 and thence after 13 years service to £1200 The Senior Medical Inspectors are eligible by selection to the four senior posts All Medical Inspectors are appointed on probation for two years If at the expiration of this time they are taken on the permanent service of the Government, the increase of pay is subject to passing such examination in Arabic as may be required by the regulations (*e*) A number of medical officers trained at one of the Syrian medical schools (*f*) A number of assistant medical officers, natives of the Sudan, who have been given a purely clinical training in one of the larger Sudan hospitals

Among the attractions of the service are The annual leave of 90 days for every year's service, which under ordinary circumstances is granted each year, study-leave for some definite purpose, and two years granted towards pension to those who have obtained special qualifications and experience The pension for a medical inspector retiring after 20 years' service is, as a rule, not less than £500 a year Private practice is limited to a few of the larger towns but may be carried on so long as it does not in any way interfere with official duties These duties include acting as consultant to the principal hospitals, and supervising smaller hospitals or dispensaries, initiating and supervising the medical and sanitary work of a province, the medical supervision of schools, the examination of candidates for Government service and pension, and the training of assistant medical officers and native sanitary overseers In the Khartoum medical school there are opportunities for teaching, the Registrar receives £250 a year, and the other teachers receive remuneration in addition to their pay The country is developing rapidly and the Medical Department is being enlarged to meet the increased requirements of the service

Four additional medical inspectors have recently been appointed, bringing the total number up to 28, and there will be further vacancies next year Candidates must be single, under 30 years of age, and they must have held a resident post, preferably house surgeon, in a large general hospital They are required to take out a course of Tropical Medicine in this country before leaving, the fees, in addition to an allowance of £4 15*s* per week during this period, will be paid by the Sudan Government

Applications for further information should be made to Dr Acland 19, Bryanston-square W 1, or to the Deans of the principal medical schools

THE DEGREE OF M D BRUSSELS

To obtain the degree of M D Brussels all foreign graduates must submit their degrees or diplomas for consideration to the Secretary of the University of Brussels According to the standard of the qualification, a period of one, two, or three years must be spent in attending lectures, clinics, and practical work at Brussels before examinations, which are conducted orally in French Further information may be obtained from Dr A D Woolf 13, The Avenue Highams Park E 4

DONATIONS AND BEQUESTS —The late Louisa E Harland of Harefield, left by will among other bequests, £1000 to the Church of England Zenana Missionary Society —Among other bequests the late Sir F G Painter left £1000 to the Bristol Infirmary for general purposes £500 each to the Bristol General Hospital the National Society for the Prevention of Cruelty to Children and the British Home and Hospital for Incurables, Streatham to present themselves for either part of the Examination must give 14 days' notice in writing to the Secretary, at the Examination Hall, Queen-square, Bloomsbury, London, W.C 1

Candidates will be admissible to Examination in Part I on producing evidence .—

1 Of being in possession of a registrable qualification in Medicine, Surgery, and Midwifery

2 Of having attended during a period of not less than five months at an Institution recognised by the Examining Board in England, practical instruction in (*a*) Bacteriology and Parasitology (including Medical Entomology) especially in their relation to diseases of man and to those diseases of the lower animals which are transmissible to man, during 180 hours, of which not less than 150 hours have been occupied in practical laboratory work. (*b*) Chemistry and Physics in relation to public health, during 90 hours, of which not less than 70 hours have been occupied in practical laboratory work. (*c*) Meteorology and Climatology in relation to public health, during not less than 10 hours.

Candidates will be admitted to Part II of the Examination on producing evidence —

1 Of having been in possession of a registrable qualification in Medicine, Surgery, and Midwifery during not less than two years, of being registered by the General Medical Council, and of having completed the curriculum for the Diploma extending over a period of 12 calendar months subsequent to the attainment of a registrable qualification.

2 Of having attended, after obtaining the registrable Qualification, instruction during not less than 80 hours at an Institution recognised by the Examining Board in England in the following subjects —(*a*) The Principles of Public Health and Sanitation for not less than 30 hours, (*b*) Epidemiology and Vital Statistics for not less than 20 hours, (*c*) Sanitary Law and Administration (including Public Medical Services) during not less than 20 hours, (*d*) Sanitary Construction and Planning during not less than 10 hours.

3 Of having attended for three months the clinical practice of a hospital for infectious diseases recognised by the Examining Board in England and of having therein received instruction in the methods of administration The Certificate must state that the candidate has attended on one or more days in each week of the three months that each attendance was of two hours' duration, with a total attendance of 60 hours

4 Of having been engaged during a period of not less than six months in acquiring a practical knowledge of the duties, routine and special, of public health administration under the supervision of a Medical Officer of Health, and of having received, from such officer or other competent Medical Officer during not less than three hours on each of 60 working days, practical instruction in those duties and also those relating to (*a*) Maternity and Child Welfare Service, (*b*) Health Service for children of school age, (*c*) Venereal Diseases Service, (*d*) Tuberculosis Service; (*e*) Industrial Hygiene, (*f*) Inspection and Control of Food, including meat and milk.

The above certificate (4) must be obtained from a Medical Officer of Health who devotes his whole time to public work, or from a Medical Officer of Health of a Sanitary Area having a population *of not less* than 50,000, or in Ireland the Medical Superintendent Officer of Health of a County or County Borough having a population of not less than 50,000.

University of Oxford.—An examination, conducted partly in writing, partly vivâ voce, and in each subject partly practical, is held in Michaelmas and in Trinity Term (until further notice in Trinity Term only) in the following subjects —General Hygiene, General Pathology (with special relation to Infectious Diseases), the Laws relating to Public Health, Sanitary Engineering, Vital Statistics. The examination is in two parts, which may be taken together or separately, but Part I must be passed either before or at the same examination as Part II The fee for admission to the examination is £10 for each part. Successful candidates are entitled to receive the Diploma in Public Health.

The First Part of the examination will comprise (*a*) written papers of three hours each in (i) Chemistry and Physics, and (ii) Pathology and Bacteriology; (*b*) a three hours' practical and vivâ voce examination in Chemistry and Physics; (*c*) a three hours' practical and vivâ voce examination in Pathology and Bacteriology.

The Second Part of the Examination will consist of the following parts:—(*a*) Two written papers, each of three hours, dealing with General Hygiene (including Sanitary Engineering, Vital Statistics, and the Laws relating to Public Health); (*b*) a practical and vivâ voce examination in General Hygiene; and (*c*) a three hours' practical and vivâ voce examination in Pathology and Bacteriology.

Candidates in Part I. of the examination will be required to produce certificates (1) of Laboratory Work in Chemistry, Physics, Meteorology, and Climatology as applied to Hygiene, and (2) of having had Practical Instruction in Bacteriology and Parasitology and the Pathology of the Diseases of Animals transmissible to Man

Candidates in Part II will produce the following further certificates: (3) of a Practical Knowledge of the Duties, Routine and Special, of Public Health Administration, and (4) of having attended the practice of a Hospital for Infectious Diseases at which opportunities are afforded for the study of the Methods of Administration

All the above degrees are now open to Women Students, and particulars of Scholarships, &c., may be obtained from the Principals of the various Ladies' Colleges The names of candidates for the Diploma in Public Health must be sent to the Assistant Registrar of the University, Clarendon Building, Oxford. Applications for any further information should be addressed to the Dean, Department of Medicine, Museum, Oxford

University of Cambridge—Two examinations in so *much of State medicine as is comprised* in the functions of medical officers of health are held during the year. The examination is divided into two parts and demands proficiency in all the branches of study which bear upon the duties of medical officers of health The examinations in both parts will be oral and practical, as well as in writing Candidates may present themselves for either part separately or for both together at their option. but the result of the examination in the case of any candidate will not be published until he has satisfied the examiners in both parts Marks of distinction will be placed against the names of candidates who have specially distinguished themselves in either (1) Part I of the examination. or (2) *Part II.* of the examination. Every candidate will be required to pay a fee of £10 10*s* before admission or readmission to *either part* of the examination Candidates must before admission to either part of the examination produce evidence of having satisfied the regulations applicable to Part I. and Part II. The examination for Part I. is in April and for Part II. in October

For Part I of the examination courses of lectures and laboratory instruction are given in the University on Hygiene Chemistry, &c, and on Bacteriology and Parasitology For Part II the Medical Officer of Health for Cambridge gives courses on Practical Sanitary Administration and in the Administrative Methods of the Infectious Diseases Hospital and the Medical Officer of Health to the Cambridgeshire County Council, on Sanitary Laws School Hygiene Epidemiology There are also courses by special lecturers in Vital Statistics Tuberculosis Service. Venereal Diseases Service, Industrial Hygiene. Maternity and Child Welfare These courses are open to non-members of the University

A special Diploma in Hygiene is granted to medical graduates whose qualifications are not registrable in England The courses and examinations are the same as for the Diploma in Public Health (except that the candidates are not examined in English Sanitary Laws)

All applications for further information respecting examinations and the courses of study should be addressed to Mr. Purvis, Public Health Chemical Laboratory, Cambridge

University of London.—Candidates for the M D Degree may offer State Medicine as a subject in which to graduate The regulations have been revised and *may* be obtained on application to the Academic Registrar, University of London, South Kensington.

University of Durham—The Degree of Bachelor of Hygiene (B Hy) and the Diploma in Public Health

DIPLOMA IN OPHTHALMIC MEDICINE

Special diplomas in ophthalmic medicine and surgery are issued by two examining bodies

University of Oxford —The diploma in ophthalmology (D.O) is granted to registered medical practitioners after passing an examination, held annually in March, which is open to candidates who have pursued at Oxford a course of study in ophthalmology over a period of at least two months and who have attended a 12 months' recognised hospital course Further information regarding these requirements may be obtained from the Dean of the School of Medicine

Conjoint Board R C.P Lond , R C S Eng —The Conjoint Board grants the D O M S after an examination held in two parts, twice yearly in January and July. Part I comprises anatomy and embryology of the visual apparatus, physiology of vision, and elementary optics Part II comprises optical defects, ophthalmic medicine and surgery, and pathology with special reference to ophthalmology The examination in each case is written, oral, and practical or clinical. Candidates may only enter for Part II. on completion of a year of special study of ophthalmology after obtaining a registrable qualification Fee for admission to each part, £6 6s.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY

This Diploma is granted by the University of Cambridge It is open only to those who hold a medical qualification, and includes a course of lectures and practical work in Physics (Part I) and in Radiology and Electrology (Part II) Attendances at the necessary course of lectures in both subjects, and, in addition, six months clinical experience in an adequately equipped hospital recognised by the Committee, are essential The whole course of study takes six months, though this is likely to be increased in the future, the lectures, practical work, and hospital attendance running concurrently Two courses of study are now recognised by the University of Cambridge One course begins in London in October in preparation for the examination in the following April, the other course begins in Cambridge in January and the examination can be concluded in the following July. In the Cambridge course three months are spent in Cambridge doing the lectures and practical work in Part I , attending the systematic lectures in Part II , and attending the practice of Addenbrooke's Hospital The remaining three months can be completed at any recognised hospital, but special arrangements are made for candidates to continue their studies in London

An independent six months course is arranged by the British Institute of Radiology This Course is held entirely in London, but is recognised by the University as qualifying for the examination, and begins early in October Further particulars as to the Cambridge Course can be obtained from Dr F Shillington Scales Medical Schools, Cambridge and of the London Courses from Dr Stanley Melville, at the Offices of the B I R , 32, Welbeck-street London, W 1

DIPLOMA IN LARYNGOLOGY AND OTOLOGY

The Conjoint Board R C P Lond , R C S Eng , grants the D L O after an examination held in two parts, twice yearly, in June and December Part I comprises anatomy, embryology, and physiology of the ear, nose, pharynx, larynx, trachea and bronchi, and œsophagus Part II comprises the medicine, surgery, and pathology of the ear, nose, pharynx, larynx, trachea and bronchi, and œsophagus, and the recognition and use of special instruments and appliances The examination in each case is written, oral, and practical or clinical Candidates may only enter for Part II on completion of one year of special study of the diseases of the ear, nose, pharynx, and larynx, after obtaining a registrable qualification The fee for admission to each part is 6 guineas

DIPLOMA IN TUBERCULOUS DISEASES

A Diploma in Tuberculous Diseases is given by the University of Wales Candidates must possess a medical qualification registrable for practice in Great Britain and Ireland, and be not less than 25 years of age, and either (Category A) have held, for a period of not less than five years, whole-time appointments for work in tuberculosis , or (Category B) have held a registrable qualification to practise for at least one year, and presented (*a*) a certificate of satisfactory pursuance of a course of consecutive post-graduate study of the clinical and epidemiological aspects of tuberculosis of six months' duration at a recognised university, medical school, or hospital where such a course is given , or, alternatively, a certificate of one year's post-graduate work as a whole-time member of the staff of a tuberculosis hospital, sanatorium, or dispensary approved by the Ministry of Health, signed by the representative of the authorities for whom the work was performed or by the administrative medical officer concerned , (*b*) a certificate of satisfactory pursuance of a course of consecutive post-graduate practical study of the Pathology and Bacteriology of Tuberculosis of three months' duration at a tuberculosis laboratory or a recognised general laboratory where such a course is given , (*c*) a certificate of three months' satisfactory attendance at a tuberculosis institute or dispensary

The examination is divided into two parts and the fee is £10 10s Applications should be made to the Registrar of the University, University Registry, Cathays Park, Cardiff, not later than May 15th

The Cecil Prosser Research Scholarship, of the value of £250 for one year, is awarded triennially for research in Tuberculosis

DIPLOMA IN PUBLIC HEALTH

THE following epitomises the instruction given at various universities and centres of medical education to medical men desiring to obtain diplomas in sanitary science, public health, hygiene or State medicine, as this discipline is variously called Resolutions, designed with a view of ensuring " the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," have been adopted at various times by the General Medical Council The diploma is registrable by the Council, whose rules on the curriculum become binding on the educational bodies concerned The new regulations, which came into force in 1923, extend the period of study and postpone the granting of a diploma until at least two years from qualification

Conjoint Board of the R C P Lond and R C S Eng New regulations came into force on Jan 1st, 1924, which apply to all candidates who have not commenced bonâ-fide study of Public Health in accordance with the above regulations before that date They are as follows The Examination consists of two Parts Part I will be held in the months of January and June, and Part II in the months of January and July in each year Candidates may enter for Parts I and II separately or at the same time, but they must pass Part I before proceeding to Part II The Examination in each part will be written, oral, and practical Part II will include a practical examination in Infectious Diseases, Food Inspection, and Inspection of selected Premises The Fee for admission to each Part of the Examination, which must be paid three days before that part commences, is £10 10s , except in the case of Candidates who possess the Licence, Membership, or Fellowship of the Royal College of Physicians of London, or the Membership or Fellowship of the Royal College of Surgeons of England, who will be required to pay £6 6s only for each part Candidates who fail to satisfy the Examiners in either part may present themselves again at the next Examination on payment of the same Fees Candidates intending administration under the supervision of a medical officer of health The examination for the diploma is divided into two parts, Part I and Part II , each of which extends over not less than two days A candidate must pass in all the subjects of Part I before being admitted to Part II of the examination In Part I , and also in Part II , a candidate must pass in all the specified subjects at one time Part I of the examination is practical, written and oral, and includes Bacteriology and Parasitology (including Medical Entomology) ; Chemistry and Physics and Meteorology and Climatology in relation to Public Health Candidates may not be admitted to Part I of the examination until they have been certified as having pursued the prescribed courses of instruction in the subjects thereof Part II of the examination, which is written and oral, includes Hygiene and Sanitation (including Sanitary Construction) ; Epidemiology and Infectious Diseases ; Sanitary Law and Vital Statistics , Public Health Administration No candidate can be admitted to Part II of the examination until after the lapse of not less than two years from the date of his obtaining a registrable qualification in Medicine, Surgery, and Midwifery, which qualification must be registered before admission to Part II of the examination An examination in each part will be held annually The examination in Part I will be held in June that in Part II in October Notice of candidature, together with the fee of six guineas for either part of the examination must be sent to the Registrar of the University University Registry. Cathays Park, Cardiff, not later than May 15th for the examination in Part I and not later than Sept 1st for the examination in Part II

University of Edinburgh—Two degrees in Science in the Department of Public Health are conferred by the University of Edinburgh—viz , Bachelor of Science in Public Health and Doctor of Science in Public Health Candidates for the degree of B Sc in Public Health must be graduates in Medicine of a recognised University, and must pass two examinations, for the first of which they must, after graduation in Medicine, have worked for at least 20 hours per week during a period of not less than eight months, of which at least five consecutive months must be in the Public Health Laboratory of the University of Edinburgh and the remainder either there or in a laboratory recognised by that University ; they must also have attended courses of instruction in Physics and Geology in some Scottish University Candidates are not admitted to the Second Examination sooner than six months after having passed the First Examination, nor sooner than 18 months after having taken their degree in Medicine, and they must have attended two separate courses in Public Health in some University of the United Kingdom or in such medical school or Indian, Colonial, or Foreign University as may be approved for the purpose by Edinburgh University, each course consisting of 40 lectures at least ; one of which courses shall deal with medicine and the other with engineering, each in its relation to public health The subjects of examination include Laboratory work, Physics, Geology, Medicine in its application to Public Health, Sanitation, Sanitary Law, and Vital Statistics Graduates who have held the degree of B Sc in Public Health from the University of Edinburgh for a term of five years may offer themselves for the degree of D Sc in Public Health in that University They must then present a Thesis and pass an examination in Public Health. The fees are £4 4*s* for the First and £5 5*s* for the Second B Sc Examinations, and £15 15*s* for the degree of D Sc

University of Aberdeen—Every candidate for the Diploma in Public Health must be a graduate in medicine of the University of Aberdeen, or of any other University whose medical degrees are recognised as qualifying for registration by the General Medical Council of the United Kingdom No candidate will be admitted to the Final Part of the Examination for the Diploma until after the lapse of not less than two years from the date of his obtaining a registrable qualification in Medicine, which qualification shall have been registered before such admission The whole of the prescribed curriculum of study must be undertaken after the candidate has obtained a registrable qualification in medicine, and shall extend over not less than twelve calendar months At least one academic term must be spent at the University of Aberdeen Every candidate shall produce evidence of having complied with the following requirements in respect of study and training —1 Practical instruction in the following subjects within a laboratory or laboratories approved by the University · (*a*) Bacteriology and Parasitology (including Medical Entomology), in relation to diseases of man and diseases of lower animals transmissible to man—at least 180 hours, of which not less than 150 shall be occupied in practical laboratory work ; (*b*) Chemistry and Physics, in relation to Public Health—at least 90 hours, of which not less than 70 shall be occupied in practical laboratory work ; (*c*) Meteorology and Climatology, in relation to Public Health—at least 10 hours ; such instruction to extend over not less than five months or two academic terms 2 A course or courses of instruction extending over not less than 80 hours dealing with (*a*) The Principles of Public Health and Sanitation—30 hours , (*b*) Epidemiology and Vital Statistics—20 hours ; (*c*) Sanitary Law and Administration (including Public Medical Services)—20 hours ; (*d*) Sanitary Construction and Planning—10 hours , such course or courses to be given at an institution or by a teacher or teachers approved by the University 3 Practical instruction, clinical and administrative, within a recognised hospital for general infectious diseases , such instruction to extend over three months, and to include 30 daily attendances of not less than two hours in each week 4 Practical instruction and experience, during not less than six months (including attendance of at least three hours on each of sixty working days) in the duties, routine and special, of public health administration, under the supervision of a medical officer of health, who shall certify that the candidate has received from this officer or other competent medical officer, practical instruction in these duties and also in those relating to · (*a*) Maternity and Child Welfare Service ; (*b*) Health Service for Children of School Age ; (*c*) Venereal Diseases Service , (*d*) Tuberculosis Service ; (*e*) Industrial Hygiene , (*f*) Inspection and Control of Food, including meat and milk The medical officers of health recognised for this purpose by the General Medical Council are (*a*) a medical officer of health who devotes his whole time to public health work or (*b*) the medical officer of health of a sanitary area having a population of not less than 50,000 : or (*c*) in Ireland, the medical superintendent officer of health of a *county or county* borough having a population of not less than 50 000 The examination for the diploma is divided into two parts, each of which extends over not less than three days The following are the fees payable for the courses of instruction given within the University · Lecture Course or Courses, £4 4*s* ; Laboratory Instruction £14 The examination fee is £8 8*s* , which is payable as follows —£4 4*s* for Part I , and £4 4*s* for Part II The fees for external instruction amount approximately to £11 11*s*

University of Glasgow—*Degree of B Sc in Public Health*—Candidates must be graduates in Medicine of a University of the United Kingdom or of some other University recognised for the purpose by the University Court Candidates must produce evidence (1) that, after they have obtained a registrable Degree in Medicine a period of not less than two years has elapsed , (2) that, after they have obtained a registrable degree in Medicine, they have, during a period of not less than 21 calendar months, pursued the course of work and instruction prescribed, and have satisfied the examiners in the prescribed examinations There are two examinations Part I. includes the following subjects . (1) Bacteriology and

(D.P.H.)—No candidate is admitted to the final examination for the Degree of B Hy unless he is a Bachelor of Medicine and Surgery, of not less than two years' standing, of a recognised University, and no candidate is admitted to the final examination for the D P H unless he is a registered medical practitioner, of not less than two years' standing The course of study for the B.Hy and D.P H extends over a period of not less than 12 calendar months, subsequent to the attainment of a registrable qualification. Candidates for the B Hy must attend this course at the University of Durham; candidates for the D P H. may attend it at the University of Durham, or at any medical school or institution which is recognised by the University. The examination for the diploma or degree is divided into two parts A candidate must pass in all the subjects of Part I. before being admitted to examination for Part II In Part I., and also in Part II, a candidate must pass in all the specified subjects at one time The examination for Part I is practical, written, and oral, and includes the following subjects Bacteriology and Parasitology (including medical entomology), Chemistry and Physics, and Meteorology and Climatology, in relation to Public Health Candidates are not admitted to examination for Part I until after they have completed the prescribed courses of instruction in the subjects thereof The examination for Part II includes Hygiene and Sanitation (including sanitary construction), Epidemiology and Infectious Diseases; Sanitary Law and Vital Statistics; Public Health Administration The examination is written and oral, and includes practical examinations in Infectious Diseases, Food Inspection, Inspection of Premises—Dwellings, Factories, Workshops, Schools, &c Candidates are not admitted to examination for Part II until after they have completed the prescribed courses of instruction in the subjects thereof The fee for the examination for the degree of B Hy. is £10 10s and for the degree £6 6s The fee for the examination for the Diploma in Public Health is £10 10s and for the diploma £3 Doctor of Hygiene (D Hy.) · Candidates must be Bachelors of Hygiene of two years' standing, and are required to satisfy the examiners that they have conducted original research in the subject of Public Health The fee for the examination is £20 and for the degree £10

Victoria University of Manchester—An examination in Public Health is held twice yearly. The examination is in two parts and is written, oral, and practical Candidates may present themselves for Parts I and II. separately or at the same time provided that no candidate be admitted to Part II unless he has already passed in Part I No candidate's name will be published until he has satisfied the examiners in both parts of the examination The fee for each part of the examination is £8 8s, and must be paid on or before July 1st in each year For any subsequent examination in the same part the fee will be £4 4s Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a Diploma in Public Health The examination will begin about the middle of July and the middle of October in each year Holders of the Diploma in Public Health are eligible for examination for the Certificates in School Hygiene and Factory Hygiene after attending the prescribed periods of study and hospital practice An examination for a Diploma in Bacteriology is held for graduates in science or medicine who have attended prescribed courses for at least one academic year, candidates must present a satisfactory thesis on an approved subject

University of Birmingham—Under the revised rules and regulations of the General Medical Council the University grants a degree of B Sc in Public Health and also a Diploma in the same subject on the following conditions Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health by conforming to all the requirements laid down for candidates for the Diploma in Public Health, except that after graduating in Medicine all courses of study must be taken out in the University, and they must, in addition, have attended a three months' course of Geology in the University. A Thesis on the Ætiology and Prevention of a Disease of which the candidate has made a special study must be submitted on entry for B Sc Part II The examinations will be held in the months of March and June and will consist of two parts, each part being written, oral and practical No candidate will be allowed to pass Part II until he has passed Part I Candidates may enter for Parts I and II separately or at the same time The fee for each part of the examination is £6 5s Medical Officers of the Royal Navy who have attended the required course of study at the Naval Medical School, Greenwich, will be admitted to Part I examinations for the Diploma in Public Health, whether they have previously been students at the Birmingham School or not, and the same applies to officers of the Royal Army Medical Corps who have studied at the Staff College Medical Officers of the Navy and Army are admitted to Part II Examination (D P H) on complying with the requirements laid down for attendance upon Courses of Study These Courses need not necessarily be attended in the University of Birmingham

University of Liverpool.—The University grants a Degree in Hygiene (M H) and a Diploma (D P H), and every facility is afforded for training in Sanitary Science and State Medicine. The curriculum for the Degree extends over a period of two years, the first of which is devoted to laboratory instruction and practical classes (including those for the Diploma); the second being devoted to advanced study and research The courses may be taken out at any time, and students are allowed to work daily in the laboratories Composition fee for M H £40 a session, and D P H £45 a course

University of Leeds—The University grants a Diploma in Public Health, and every facility is afforded for training in Sanitary Science and State Medicine The examination, which is held twice in each year—namely, in June and December—is in two parts, and is written, oral, and practical Candidates must pass in Part I before being admitted to Part II Fees—The fee for each part is £6 6s, and for any subsequent examination in the same part £4 4s Instruction in Entomology and Meteorology is given in the first term, and in Sanitary Chemistry and Bacteriology in the second and third terms Practical work under arrangement with the Leeds City Council Prospectus can be obtained from the Academic Sub-Dean of the Medical School

University of Bristol—Diploma in Public Health Candidates must be at least 23 years of age shall be fully registered medical practitioners of not less than two years' standing as such, and shall have passed the examination prescribed by regulation The examination is divided into two parts

University of Wales—Candidates for the Diploma in Public Health, the curriculum for which extends over a period of not less than twelve calendar months subsequent to the attainment of a registrable qualification, must produce evidence of having attended for not less than five months at the Welsh National School of Medicine or at an institution approved by the Court, practical instruction in Bacteriology and Parasitology, Chemistry and Physics, and Meteorology and Climatology in relation to Public Health Candidates must also satisfy the examiners that they have received instruction approved by the University in the Principles of Public Health and Sanitation, Epidemiology and Vital Statistics, Sanitary Law and Administration, and Sanitary Construction and Planning The candidate must also produce evidence that he has attended for three months on the clinical practice of a hospital for infectious diseases containing not less than 100 beds, and has received therein instruction in the methods of administration, and that he has for a period of not less than six months been engaged in acquiring a practical knowledge of the duties, routine and special, of a public health *tion have been adjusted fully to meet the requirements of the regulations of the General Medical Council which came into force on Jan 1st, 1924.* Candidates applying for Regulations should state date of commencement of curriculum The Registrar for Edinburgh is Mr D L Eadie, 49 Lauriston-place, and for Glasgow Mr Walter Hurst 242, St Vincent-street

Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland—Every candidate for the Diploma in Public Health must observe the following rules 1 A period of not less than two years shall elapse between the attainment by a candidate of a registrable qualification in Medicine Surgery, and Midwifery, and his admission to the Final Examination for a Diploma in Public Health 2 The curriculum for a Diploma in Public Health shall extend over a period of not less than 12 calendar months subsequent to the attainment of a registrable qualification 3 Every candidate shall produce evidence of having attended during a period of not less than five months, at an institution approved by the Licensing Body granting the Diploma, practical instruction in—(*a*) Bacteriology and Parasitology (including Medical Entomology), especially in their relation to diseases of man, and to those diseases of the lower animals which are transmissible to man, (*b*) Chemistry and Physics in relation to Public Health, (*c*) Meteorology and Climatology in relation to Public Health At least 180 hours must be devoted to Course (*a*), of which not less than 150 hours shall be occupied in practical Laboratory work At least 90 hours must be devoted to Course (*b*), of which not less than 70 hours shall be occupied in practical Laboratory work At least 10 hours must be devoted to Course (*c*) 4 Evidence of having received, during not less than 80 hours, at an institution or from teachers approved by the Licensing Body granting the Diploma, instruction in the following subjects: (*a*) The Principles of Public Health and Sanitation, (*b*) Epidemiology and Vital Statistics, (*c*) Sanitary Law and Administration (including Public Medical Services), (*d*) Sanitary Construction and Planning 5 Evidence that he has attended for three months on the clinical practice of a recognised Hospital for Infectious Diseases 6 Evidence that he has during a period of not less than six months, been engaged in acquiring a practical knowledge of the duties, routine and special, of Public Health Administration under the supervision of a Medical Officer of Health The examination for the Diploma is divided into two parts The examination for Part I includes Bacteriology and Parasitology (with Medical Entomology); Chemistry and Physics and Meteorology and Climatology, in relation to Public Health The examination for Part II includes Hygiene and Sanitation (with Sanitary Construction), Epidemiology and Infectious Diseases, Sanitary Law and Vital Statistics; Public Health Administration The examination, which is written and oral, includes practical examinations in Infectious Diseases, Food Inspection, Inspection of Premises—dwellings, factories, workshops, schools, &c

DENTAL SURGERY

ANYONE who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without degree or licence in dentistry, but it is a distinct advantage to take a special dental qualification, otherwise few dental appointments at general or special hospitals or dispensaries are available

THE DENTAL BOARD OF THE UNITED KINGDOM.

Under the Dentists Act, 1921, the powers and duties of the General Medical Council under the Dentists Act, 1878, and under the Medical Act, 1886, which related to the keeping of the Dentists Register and the administration of the Dentists Acts were largely transferred to the then newly-constituted Dental Board of the United Kingdom The registration of dental students at the commencement of their dental studies, and the right of erasure of a name from the Dentists Register, remain with the Council, but the duty of inquiring into disciplinary cases rests with the Board, upon whose recommendations the Council acts

The Dental Board consists of a chairman and 12 members The following are the names and sources of appointment of the members: Chairman of the Board, Rt Hon F Dyke Acland, appointed by the Privy Council Members of the Board: Mr L G. Brock, C B appointed by the Minister of Health; Mr A Young, appointed by the Scottish Board of Health, Mr J H Stirling, appointed by the Governor-General of Northern Ireland, Sir Holburt Waring, M S, F R C S, Sir James Hodsdon, K B E, F R C S Edin, Mr. T Sinclair, C B, F R C S, M P, appointed by the General Medical Council, Mr W R Ackland, M.D S, M R C S; Mr W H Dolamore, L D S, M R C S, elected as Direct Representative by the qualified dentists practising in England and Wales, Mr W Guy, L D S, F R C S, elected as a Direct Representative by the qualified dentists practising in Scotland, Mr. J J Andrew, L.D S, elected as Direct Representative by the qualified dentists practising in Ireland, Mr W. F Bowen and Mr F. Butterfield elected as Direct Representatives by registered dentists not being qualified dentists. Treasurers of the Board, Sir Holburt Waring and Mr. W H Dolamore Registrar of the Board, Mr N C. King

The offices of the Board are at 44, Hallam-street, London, W 1, adjoining the offices of the General Medical Council.

REGISTRATION OF DENTAL STUDENTS

The following are the General Medical Council's Regulations in regard to the registration of dental students which came into force on Jan. 1st, 1923

The Council recommends that, subject to such exceptions as the Council may from time to time allow, every dental student at the commencement of his studentship should be registered in the manner and under the conditions hereinafter set forth.

1. The registration of dental students shall be carried on at the General Medical Council Office in London, in the same manner as that of medical students, and is subject to the same regulations as regards age and preliminary examinations, but in the case of dental students professional study may commence by pupilage with a registered dental practitioner

2 Candidates for a diploma in dental surgery should produce certificates of having been engaged for at least four years in professional studies, and of having received during 24 calendar months instruction in mechanical dentistry (see No 3 below)

3 It is recommended that instruction in dental mechanics be taken at a recognised dental hospital and school. If any part of such instruction be taken by the candidate as a pupil with a registered dental practitioner, the time required to be devoted to it shall be at least twice the time required for the corresponding instruction taken at a dental school

4 Two years' bona-fide apprenticeship with a registered dental practitioner, after registration as a dental student, may be counted as one of the four years of professional study.

5 The necessary instruction in dental mechanics, or any part of it, may be taken by the dental student either before or after his registration as a student When a student can show evidence of regular pupilage in dental mechanics to a registered practitioner, prior to the passing of the prescribed preliminary and scientific examinations, he may be allowed to antedate his registration for a period not exceeding one year prior to the passing of these examinations (see No 3 above).

EXAMINING AND TEACHING BODIES IN DENTISTRY

The list of the Examining Bodies in Dentistry which grant diplomas or degrees in this subject and the regulations for obtaining these qualifications

Parasitology (including Medical Entomology), (ii) Chemistry and Physics in relation to Public Health; (iii) Meteorology and Climatology in relation to Public Health, (iv) Higher Chemistry in relation to Public Health, (v) Physics and Geology. A candidate must pass in the subjects marked (i), (ii), and (iii) of Part I. at one examination. Part II. includes the following subjects: (vi) Hygiene and Sanitation (including Sanitary construction), (vii) Epidemiology and Infectious Diseases, (viii) Sanitary Law and Vital Statistics, (ix) Public Health Administration, (x) Applied Hygiene. The examination for Part II. includes practical examinations in Infectious Diseases; Food Inspection, Inspection of Premises, such as dwellings, factories, workshops, schools, and the like. The examination in Applied Hygiene may be on a selected subject professed by the candidate. A candidate must pass in the subjects marked (vi), (vii), (viii), and (ix) of Part II. at one examination. *Diploma in Public Health (D.P.H.)*.—Candidates for this Diploma must be legally qualified medical practitioners who are matriculated students of the University. A period of not less than two years must elapse between the attainment by the candidate of a registrable medical qualification, and his admission to the final examination (Part II.) for the Diploma. The candidate must, during a period of not less than 12 calendar months, subsequent to his attainment of a registrable medical qualification, pursue the course of work and instruction prescribed, and pass the prescribed examinations. The examination, which is both written and oral, is divided into two parts, Part I. and Part II., each of which extends over not less than two days. No candidate is admitted to either part of the examination until he has completed the prescribed courses of instruction in the subjects of that part. No candidate is admitted to Part II. until he has passed in all the subjects of Part I., nor until after the lapse of not less than two years from the date of his obtaining a registrable medical qualification, nor unless he presents a certificate showing that his name and qualification have been duly registered in the Medical Register. Part I. includes (i) Bacteriology and Parasitology (including Medical Entomology), (ii) Chemistry and Physics in relation to Public Health, (iii) Meteorology and Climatology in relation to Public Health. A candidate must pass in all the subjects at one examination. Part II. includes (iv) Hygiene and Sanitation (including Sanitary Construction), (v) Epidemiology and Infectious Diseases, (vi) Sanitary Law and Vital Statistics, (vii) Public Health Administration. A candidate must pass in all the subjects at one examination. The examination for Part II. includes practical examinations in Infectious Diseases, Food Inspection, Inspection of Premises, such as dwellings, factories, workshops, schools, and the like.

University of St. Andrews.—The Diploma in Public Health is open to those who hold a registered medical qualification of the United Kingdom. The examination is in two parts. (1) (*a*) Bacteriology and Parasitology, (*b*) Chemistry and Physics, (*c*) Meteorology and Climatology. (2) Public Health and Sanitation, Epidemiology and Vital Statistics, Sanitary Law and Administration, and Sanitary Construction and Planning. Before admission to the first examination the candidate must have held his medical qualification for one year, and before admission to the second examination for two years. Graduates in Medicine of the University of St. Andrews may take part or all of the qualifying classes in any University of the United Kingdom or in any Indian, Colonial, or Foreign University or medical school recognised by the University Court, but holders of other registered medical qualifications must spend at least eight out of the 12 months' curriculum in St. Andrews University. A complete course is given in the Conjoint Medical School, Dundee. The examination fee for each division is £5 5*s*.

University of Dublin (Trinity College).—The Diploma in Public Health is conferred, after examination, under the following conditions. The candidate must be a registered medical practitioner and have obtained a registrable qualification at least two years before the second part of the examination. The candidate must have completed, subsequently to obtaining a registrable qualification, five months' practical instruction in a chemical and bacteriological laboratory, or laboratories, approved by the University, must have received instruction in the following subjects: the principles of public health and sanitation, epidemiology and vital statistics, sanitary law and administration (including public medical services), sanitary construction and planning, must have studied, practically, outdoor sanitary work for six months under an approved officer of health, and must have attended for three months at a fever hospital where opportunities are afforded for the study of methods of administration. A special prospectus may be obtained by application to the Registrar of the School of Physic, Trinity College, Dublin.

National University of Ireland *.—At this University there is a Diploma in Public Health, a B.Sc. in Public Health, and a D.Sc. in Public Health.

University of Belfast.—A Diploma in Public Health is given by examination. Every candidate must produce evidence that, after obtaining a registrable qualification, he has during six months received practical instruction in an approved laboratory in which Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man are taught. After obtaining a registrable qualification every candidate must produce evidence that he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. The examination must have extended over not less than four days, one of which shall have been devoted to practical work in a laboratory, and one to practical examination in, and reporting on, subjects which fall within the special outdoor duties of a medical officer of health. The examination will be held in two parts, in March and in June. The first part of the examination will have reference to the general principles of Sanitary Science and the second part to State Medicine and to the applications of Pathology and Sanitary Science. The fee for each part is 2 guineas.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, Royal Faculty of Physicians and Surgeons of Glasgow.—All candidates for the Diploma in Public Health must have a qualification which has been registered under the Medical Acts. Candidates must have attended not less than four calendar months' practical instruction in Chemistry and Physics (90 hours), Bacteriology and Parasitology (180 hours), and Meteorology and Climatology (60 hours) in a recognised laboratory or laboratories, must have studied outdoor sanitary work for six months under a medical officer of health or other sanitary officer, and must give evidence of attendance for three months at the practice of a Hospital for Infectious Diseases, at which he has received instruction in the methods of administration. The examination consists of two parts, and candidates may enter for both at one period or for either separately. The First Part includes (*a*) Laboratory Work (Chemistry and Bacteriology), (*b*) Physics and Meteorology, and the Second Examination embraces (*a*) Report on Premises visited, (*b*) Examination at Fever Hospital, (*c*) Examination at Public Abattoir, (*d*) Written and Oral Examinations on Epidemiology and Endemiology, (*e*) Vital Statistics and Sanitary Law, and (*f*) Practical Sanitation. The fee is 12 guineas for both examinations, or 6 guineas for either of them. A fee of 3 guineas is payable by rejected candidates for either. The examination is held twice yearly, in May in Glasgow, and October in Edinburgh. The published regulations provide detailed synopses of the subjects of examination. *The curriculum and examina-*

An Address
ON THE
PSYCHOSES AND THE PSYCHONEUROSES
CONTRASTED FROM A PSYCHOLOGICAL POINT OF VIEW

(Abridged from a Lecture to the Manchester University Psychological Society.)

By HENRY YELLOWLEES, M.D. Glasg.,
F.R.C.P. Edin., D.P.M.,
MEDICAL SUPERINTENDENT, THE RETREAT, YORK

We are to consider the differences between the psychoses and the psychoneuroses, particularly from a psychological point of view, and this subject is one which has never been, to my knowledge, really seriously tackled. The reasons for this are numerous, and some of them are interesting. To begin with, the question is one of quite unusual difficulty, and secondly, these groups of cases which we are to compare and to contrast—the psychoses on the one hand and the psychoneuroses on the other—have, up till comparatively recent years, been largely neglected by the great majority of scientific workers, and have, indeed, vied with each other for the title of the Cinderella of medical science.

A final reason why the subject has not been so thoroughly opened up as it might and should have been is that between the alienist and the psychologist there is a great gulf fixed, and the opinions which they reciprocally hold of each other are not those calculated to produce an atmosphere favourable for the satisfactory investigation of the matters which lie between them. It has seemed to me that each side is none too capable of seeing the other's point of view and just a trifle depressed at the lack of hopefulness in the outlook from its own, and that the cries of each have a touch of despair as well as defiance.

Preliminary Definition

The first thing we must do is to make clear what we mean by the psychoses. I propose to cut them down for the purpose of this discussion to the big three which are the typical "insanities" and stand out, mysterious, forbidding, and apparently inexplicable among many more comprehensible states of minor importance.

We shall exclude general paralysis of the insane because it has the bodily disease of syphilis as its proved essential causative factor. We shall eliminate the acute confusions and deliria as being demonstrably due to infections; nor are we at the moment concerned with developmental failures resulting in idiocy and imbecility, nor with degenerative changes giving rise to senility and the dementias. Epilepsy also is not our present concern, and we are left, as I say, with the three typical psychoses: the manic-depressive psychosis, paranoia, and dementia præcox. It will be remembered that these are far from being the entire content of psychiatry, and that whenever the psychoses are referred to here I am definitely limiting the phrase to mean these three only. Over against them let us put a representative selection of the typical neuroses and psychoneuroses: for example, anxiety states, neurasthenia, the obsessional states, and hysteria. I shall call these collectively the "neuroses" as shorter and less likely to be confused with "psychoses" than the longer word "psychoneuroses." Now, sufferers from the first-named group are what we call "insane." Those who suffer from the second are not, and we return to the question of why we say this, and to the task of comparing and contrasting them from the psychological point of view.

Pathology

First, as by duty and tradition bound, we turn to look at their pathology, using this word in its meaning of demonstrable morbid histology and anatomy. We are not detained long because we find that neither group has any pathology at all. No one to my knowledge has demonstrated or attempted to demonstrate any constant change in brain or bodily structure to account for a single one of the morbid conditions we have named. We have, it is true, Mott's work upon the changes in the gonad cells in dementia præcox, but beyond his statement that this disorder is accompanied by regressive atrophy of these cells the rest is silence. Disappointed here, we turn to the new psychology for aid, and find a most interesting state of affairs. We find, without for the moment discussing whether it is based on fact or theory, that all the neuroses have a psychopathology which is logical, practical, wonderfully complete, and perfectly intelligible to those who are prepared to try to understand it. When we come to the psychopathology of the psychoses we find that there is one indeed, but it is obscure, abstruse, complicated, thoroughly involved, and leads nowhere. Freud on hysteria is a real joy, Freud on melancholia is a terror, and in addition gives one a headache. One turns from studying the Freudian explanation of any true psychosis with a kind of vicious delight to the passage in which McCurdy blandly remarks: "It is conceivable that Freud and his disciples are as ignorant of psychiatry as their statements imply."

I must digress here to say just one more word about the controversy between alienist and neo-psychologist in this relation.

The new psychologists seem to me to fail firstly because they are, broadly speaking, entirely and gloriously ignorant of clinical psychiatry. They know nothing really worth mentioning about the clinical symptoms, course, management, and treatment of the psychoses. Secondly, they apply their psychopathology, *secundum artem* (which sometimes means by rule of thumb), to every case which comes their way, and do not rest until they have reduced it to a formula which meets with their own entire satisfaction. The attitude of the average alienist is almost too terrible to talk about. Irritated no doubt by the *deus ex machinâ* attitude of the psychologist, he expresses himself with great force and heat, and an almost entire absence of light. All psychology, psychopathology, and psychotherapy are represented to him by the one word "Freud," whom he regards much as our grandfathers regarded a personal devil, only there are sadly few alienists who believe that "the Prince of Darkness is a gentleman." I may add that this attitude is by no means confined to alienists, but is shared by surgeons, obstetricians (strangely enough), X ray specialists, and, indeed, by most who possess the one necessary qualification—namely, an untrammelled ignorance of the entire subject. I sometimes wonder if they regard an open mind and a vacant mind as synonymous terms. The extraordinary thing is that those who tell us most forcibly of the villainies of Freud and those who explain most clearly just where he has failed do so in the very language which he has made part of the current coin of our specialty. We cannot discuss a case without using some of Freud's conceptions and terms, and it is a tragic thing to hear the anti-Freudian alienist describe a case from what he fondly imagines is an anti-Freudian point of view in Freud's very own words and phrases borrowed, or perhaps I should say stolen, for the occasion.

The truth of the matter is simply this, that if you regard the unconscious mind as a myth, and therefore the whole of Freudian psychology as utter and total rubbish, it is quite impossible to get very far in many directions, among them that of our present discussion. A broad view of the psychoses and any investigation of their relation to the neuroses is out of the question if one is too proud, too ignorant, or too bigoted to take the new psychology as even a working hypothesis. That it fails, and fails egregiously will appear in a guide to teaching institutions in dentistry at a later date

In addition to facilities provided by the various Universities, Colleges, and Faculties, a number of dental courses are available In London at the Royal Dental Hospital (School of Dental Surgery), Leicester-square, at University College Hospital Dental School, and at the Dental Departments of Guy's Hospital and of the London Hospital In the provinces at the Birmingham, Manchester, and Newcastle-on-Tyne dental hospitals. In Scotland at the Incorporated Edinburgh Dental Hospital, the Incorporated Glasgow Dental Hospital, and the Dental Department of Glasgow Royal Infirmary In Ireland at the Incorporated Dental Hospital of Ireland, Dublin Dental study may be commenced also at any of the following schools Birmingham Dental Hospital, Bristol Royal Infirmary and General Hospital, Dundee Dental Hospital, Leeds Dental Hospital. Liverpool Dental Hospital, and Sheffield Royal Hospital

PRISON MEDICAL SERVICE

CANDIDATES for the Prison Medical Service are approved by the Secretary of State for the Home Department on the recommendation of the Prison Commissioners Preference is always given to candidates who have experience of lunacy Application for employment may be made on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S W 1 In the smaller prisons the medical officership is part-time, and is usually filled by practitioners in the locality, preference being given to those who have special experience of lunacy In the large prisons the medical staff must devote their whole time to the Service In the case of whole-time service, the appointment is in the first instance to the post of Medical Officer Class II, and from the seniors of this rank the Medical Officers, Class I are selected as vacancies occur The pay of the whole-time prison medical staff is as follows Medical Officer, Class II, £350, rising by annual increments of £20 to £600, making the pay at present with bonus £504 14*s* to £801 11*s*, Medical Officer, Class I £650, rising by annual increments of £25 to £800, plus bonus, making the pay £864 to £1023 9*s* Unfurnished quarters are provided or an allowance in lieu is made Study leave is granted annually to two of the whole-time Medical Officers There are 12 full-time medical officers of Class I and 15 Class II, and 23 part-time medical officers The number of vacancies is never large and promotion is slow In the case of a part-time medical officer, the population of the prison is the basis of fixing the salary unless there are some special features justifying special consideration

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 14TH, 1926

Notifications —The following cases of infectious disease were notified during the week —Small-pox, 74 (last week 60), scarlet fever, 1170, diphtheria, 799, enteric fever, 73, pneumonia, 396, puerperal fever, 40, cerebro-spinal fever, 8, acute poliomyelitis, 37, acute polio-encephalitis, 3 encephalitis lethargica, 42, relapsing fever 1, continued fever 1, dysentery, 9, ophthalmia neonatorum, 113 There were no cases of cholera, plague, or typhus fever notified during the week

Deaths —In the aggregate of great towns, including London, there were no deaths from small-pox, 1 (0) from enteric fever, 9 (0) from measles, 6 (1) from scarlet fever, 20 (0) from whooping-cough, 23 (8) from diphtheria, 85 (17) from diarrhoea and enteritis under 2 years of age, and 18 (3) from influenza The returns for diarrhoea and enteritis show a small rise for the Great Towns and a drop for London, compared with the figures of the previous week The figures in parentheses are those for London itself

MEDICAL DIARY

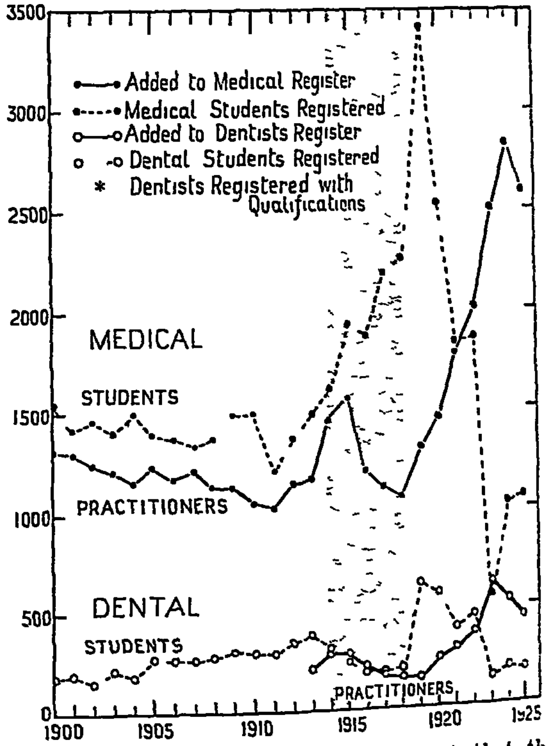
POST-GRADUATE HOSTEL Imperial Hotel Russell sq, W C

WEDNESDAY Sept 1st —9 P M Dr L R Yealland will open a discussion on Seizures

FRIDAY Sept 3rd —9 P M Dr A L Gregg will open a discussion on the Sigmoidoscope in Diagnosis All medical practitioners cordially invited

THE PORTAL OF MEDICINE

THE graph here given shows the numbers of students and graduates entering the medical and dental professions in each year from 1900 to 1925 The stippled band represents the period of hostilities, 1914–1918



The asterisk calls attention to the fact that the curve of dental practitioners includes only those who registered with qualifications The total number of dental entries, including those registered under the Dentists Act, 1921, is 734 for 1924 and 524 for 1925

THE Therapeutic Substances Act, 1925, provides that the Regulations to be made under the Act shall be framed by a Joint Committee consisting of the Minister of Health, the Secretary for Scotland, and the Minister of Home Affairs for Northern Ireland It is provided under Section 4 (2) that for the purpose of assisting the Joint Committee in framing the Regulations there shall be an Advisory Committee The Advisory Committee has now been constituted as follows Sir George Newman, K C B, M D (the Ministry of Health) chairman, Mr John Jeffrey (Scottish Board of Health), Dr Thomas Houston (Ministry of Home Affairs for Northern Ireland), Dr H H Dale (Medical Research Council), Sir Nestor Tirard (General Medical Council), Dr C O Hawthorne (British Medical Association), Dr J H Burn (Pharmaceutical Society of Great Britain), Dr J F Tocher, F I C (Institute of Chemistry of Great Britain and Ireland)

A preliminary prospectus has been issued of a Universal Smoke Abatement Exhibition to be held in Birmingham from Sept 6th to 18th

---

FACTORY GIRLS COUNTRY HOLIDAY FUND —An urgent appeal signed by Lady Sandwich, the Bishop of Kensington Sir Thomas Barlow Dame Mary Scharlieb, and others has been issued on behalf of the Factory Girls' Country Holiday Fund, which sends away to the country women and girls of the crowded and airless districts of London for a week or a fortnight Many of these are the main support of their families Subscriptions and donations should be sent either to the Chairman, Mr J F Green, 42, Upper Mall, Hammersmith, W 6 or to the Secretary, 75, Lamb's Conduit-street, W C 1 knows that he is ill, whereas the second one does not· Let us pursue this question of insight a little further Every sufferer from a neurosis has got insight into his condition He knows that he is ill and also that it is his nervous system which is at fault The neurasthenic knows that he has neurasthenia and can be got to discuss his case with a remarkable detachment Even the hypochondriac realises that his illness does not lie in the various organs of his body with which he is concerned, but in his preoccupation with them The antics of the obsessional patient cannot appear more absurd to others than they do to himself and the hysteric, save when he is actually in a hysterical fugue, has a very much clearer realisation of his case and everything connected with it than we are apt to give him credit for An additional proof of the presence of insight in these conditions is, of course, their amenability to psychotherapy All methods of psychotherapy demand a certain degree of insight into his own condition on the patient's part, and without this no psychotherapy is possible.

INSIGHT.

Now, what of insight in the psychoses? In dementia præcox, as in paranoia, the entire absence of *insight is one of the most striking features* The patient has absolutely none The only psychosis in connexion with which the question is even arguable is manic-depressive insanity The manic phase we can dismiss at once Anyone who has to do with an elated patient knows that complete loss of insight is one of the earliest symptoms of elation We are left with melancholia, that most elusive and baffling condition of all Practically every book and every teacher that I have known has insisted that the melancholic patient has invariably a well-nigh complete insight into his condition It is so tempting The patient preserves his memory, his intelligence, his modesty, and his dignity. He retains as a rule what he has of sensitiveness and refinement It seems, and is, an outrage to utter the word "lunatic" in connexion with him, and his friends have the most extreme difficulty in realising that he is mentally ill at all You would, in fact, need to have a pretty extensive acquaintance with melancholics to realise that it takes a certain amount of courage to say what I tell you now—namely, that, in spite of all this, I do not believe they have any insight worth talking about in the proper sense of the term The melancholic will tell you how long he has been ill, but if asked whether it is an illness or a wickedness, he will, nine times out of ten, plump unhesitatingly for the latter He will discuss his case with a brave effort at detachment, if his case is sufficiently mild, but, though he has recovered from six previous attacks, you will never get him to believe that recovery from this one is even a possibility let alone a moral certainty He may possibly admit to being ill, but if so, he regards his illness as the result of his having failed in some duty, given way to some temptation, lost his power to pray, and so on, instead of regarding these ideas as the *consequences* of his illness No one who so persistently and inevitably puts the cart before the horse as the melancholic does on every possible occasion can fairly be regarded as having insight into his condition And if this is true of the kind of case I have been describing, much more is it true if the attack is in the least a serious or severe one That man has surely no insight who can hold with a grim certainty that he is damned for ever, who can quietly wait and plot and plan for an opportunity to end an intolerable existence, who can believe that death is the only solution for the mass of perplexities, miseries, and hopelessness which surrounds him, and who regards the responsibility for a lost world as being upon his shoulders—all because he did not go to a certain doctor or post a certain letter The melancholic has no insight, and our touchstone holds good In spite of all kinds of exceptions, qualifications, and modifications I know of no better and indeed of no other, means to judge whether we are dealing with a psychosis or a neurosis, than to apply this test of insight

But, with that point gained, are we really much further forward? Let us see just how we stand. The neuroses arise from external causes and the patient retains his insight The psychoses arise from some cause inherent in the patient himself, and are characterised by a loss of insight That sounds well, and it could be worked out into an extremely neat and comprehensive scheme, provided that one ignored one or two rather troublesome difficulties, the chief of which prompts the question: If that is so, why does manic-depressive insanity recover? As a matter of fact, this difficulty seems greater than it really is. All that it does is to force us to be more vague than we would like to be as to the precise nature of this inherent cause, and to give us more sympathy with those who use words to conceal ignorance It is easy enough to postulate some biological defect which, as it were, foreordains a patient to paranoia or dementia præcox, in connexion with which last, indeed, Mott speaks of "an inherent defect in the fertilised ovum" as the beginning of all the trouble, but it is a different and a harder thing to postulate any parallel defect or abnormality which will produce periodic attacks of mania or melancholia at irregular intervals, the recurrences being, very possibly, quite unconnected with external stresses and strains One easy way out is to exclude manic-depressive insanity from the psychoses altogether, but as by every other imaginable test it belongs to them, this cannot fairly be done. Or one might attempt to tuck it away among the, so to speak, accidental psychoses, such as the various infections and confusional states, but there are also many objections to this Efforts have been made for years to demonstrate an infective origin without success, and also we have to deal with the fact that the manic-depressive psychosis or the liability to it is quite definitely inherited though admittedly not so obviously and inevitably as dementia præcox. We shall, therefore, have to stick to our ground and regard it as a constitutional psychosis Finally, we can go on the very opposite tack and throw doubt upon the genuineness of the recoveries in manic-depressive insanity, and point out that even the "diehards" admit that a large proportion of the cases have what they call a "dementia præcox colouring," and that a slight but progressive deterioration may be observed after the so-called recovery from each attack We can also make ingenious play with the tendency to recurrence, and try to correlate this with developmental epochs in the life of the individual Whatever we do, the nasty little snag remains as an obstacle to a pretty scheme

DIFFERENTIATION

I am now going to make a final attempt at differentiation from as purely a psychological point of view as I can, although, from what I have said, the limitations of that view in connexion with the psychoses ought to be obvious What does this symptom of loss of insight really amount to? Surely from a psychological point of view insight is the supreme indication of effective hold on reality. I have insight into my state of mind That is to say, I can look at it with reasonable detachment and see it as it really is In other words I am in touch with reality The reverse is the case, whatever the appearance may be, when I have no insight Now, assuming for the moment that the unconscious mind is not quite the myth which many authorities whom I might quote would have us believe—in fact, accepting the Freudian psychology for the time being—it will be remembered that it is the conscious mind which works under the reality principle and the unconscious mind which works in a primitive kind of way under the pleasure-pain principle In short, the conscious mind is in direct touch with reality and the unconscious mind is not I should say here that the main idea of what follows is borrowed from McCurdy, and no doubt marred in the borrowing We know, of course, that although the unconscious mind is a highly dynamic in many respects, is beside the point Without it, we have nothing whatever to go on and need not begin

I ask you now to return with me to consider the *course* of these two groups of illnesses Sufferers from the neuroses, broadly speaking, respond to treatment and recover We need not consider for the moment what kind of material they were to start with, and I am not concerned to deny that many of them may be very C 3 persons after recovery in some cases The immediate point is that they do recover

What about the psychoses? Again, broadly speaking (because associated with every group we always find a few cases which are like nothing in heaven or earth, and conform to no rules but their own), we find that dementia præcox does not recover, that paranoia does not recover, and that the manic-depressive psychosis recovers indeed, and that perfectly, as far as any given attack is concerned, but shows a remarkable tendency to periodic recurrence That is all we need say about the course of these illnesses, because it is intimately bound up with the question of treatment which we shall now consider

TREATMENT

I must first remind you of the varying meanings which the word "treatment" may have If we use it in as limited a sense as possible, and make it mean direct curative treatment, we can give such instances as the use of quinine in malaria, of salvarsan in active syphilis, and a few, a very few, other drugs, which are what we call specifics for certain conditions They will *cure* them Broaden the meaning of the word just a little and consider the treatment of, say, pneumonia There is no direct curative treatment for pneumonia That is to say, so far as we know, no power on earth will hasten the crisis or delay it from coming when it will come, somewhere about the seventh to the ninth day I need not tell you, of course, that the way in which we treat the patient is frequently the determining factor in whether or not his strength will hold out until the crisis comes, but we are treating his symptoms in the hope that he will be able to stand the strain until his pneumonia has treated itself. Going further still, we see the same principle almost more clearly in cases of, say, valvular heart disease Here we can relieve dyspnœa, cyanosis, and pain, time and again, but we can never correct the faulty mechanical action of the pump, and it will defeat us in the end Finally, we have the treatment, so-called—and properly so-called—of such a condition as inoperable cancer, where the battle is a losing one from the start, and all we can do is to keep the patient as comfortable as we can until his brief hour upon the stage is over, and see to it, if we can, that the curtain falls quietly

Do not forget that all these things are treatment in varying senses of the word In which sense can we claim that there is treatment for the illnesses we are considering?

In the strict and narrow sense of direct cure there is no treatment which will cure a psychosis any more than there is treatment which will "cure" a pneumonia before it has run its course When we turn to the neuroses we find the astonishing fact that there *is* direct curative treatment for them—treatment without which, broadly speaking, they will not get well, and with which they are definitely curable, whatever their duration or severity Further, the treatment is practically always psychotherapeutic, though I am not concerned to argue that it is invariably so, nor do I give *credit* to any one method of treatment more than another I do not even deny that in some cases the cure may be but temporary, or that some few cases may be apparently incurable I am only anxious to emphasise the undoubted clinical fact that cures and responses to treatment occur with a promptitude and definiteness, and to an extent, to which the true psychoses can show no parallel

CAUSATION

With these outlined points of difference in our mind we shall now have to leave clinical fact and go more into theory, not to say speculation Let us look at the causation of these conditions As regards the neuroses is it not true that in the last resort the causes lie in upbringing, environment, and the effects of external circumstance? Analysis and psychopathology surely make this plain They dissect out the devious paths by which the particular neurosis in question became established—the unwise teaching, the one-sided upbringing, the impossible home environment, followed by the repressions, the inadequate sublimations, the regressions—and we are left with the feeling that if only the unfortunate patient had got into the right hands early enough he need never have become a patient at all To put the matter in a word, neurotics, generally speaking, are made, not born I believe it to be far otherwise with the psychoses, the causes of which are more deeply and mysteriously biological Psychotics are born, not made We can—and unfortunately we often do—create neurotics, but the longer I study psychiatry the more surely do I feel that the sufferers from the typical psychoses we are discussing have been ordained to them, as it were, from the foundation of the world Psychopathology may explain their superstructure and elucidate their *content* with greater or less success, but in any case it leaves untouched that deeper *something* which is their essential foundation Hence we are drawn to the conclusion—and it is one of the most far-reaching importance—that in spite of all superficial resemblances in symptoms, mechanisms, or anything else, there is, in fact, a great gulf fixed between the two Many a man can say—as I can say myself—that I can quite well imagine circumstances in which I might become neurasthenic, or hysteric, or obsessional, but I *know* that I shall never become insane.

What this inherent something in the potential psychotic is, how *precisely* it acts, and how it comes to be there at all are questions to which we have, frankly, no thoroughly satisfactory answer, though of course there are those for whose modest requirements the solemn phrase "hereditary predisposition" goes deep enough It is possible, indeed, that this may be all we may ever be able to say, but it is at least worth while to offer a tentative suggestion or two as to what that phrase may possibly imply

If it be true that there is this very distinct cleavage in ætiology between the psychoses and the neuroses, it should surely be reflected in some way or other in their respective symptoms There should surely be something common to the insanities which is not found in the neuroses, or vice versa, something running through all the varieties and cases of one or other of the groups which might give us some lead as to how to study the precise nature of the essential difference between them

We say in our breezy way that people suffering from the psychoses are mad, and people who are suffering from the neuroses are sane, and that is all about it When you come to think about the subject carefully, however, you will find that there are few harder tasks than to put into words any kind of general characteristic which divides the sane from the insane On the face of it, an insane person suggests *to us* someone whose conduct in one respect or other is grossly incompatible with the demands of society, but this suggestion is, in fact, unfair to *both* sides, quite apart from the few doubtful cases which exist on every borderline A very large proportion of the demonstrably insane can conform to society's rules with considerably more apparent success than many a neurotic.

BODILY AND MENTAL ILLNESS CONTRASTED

We shall perhaps arrive most readily at the touchstone for which we are seeking by *contrasting* bodily with mental disease What is the most striking difference, over and above the difference of detailed symptoms—the most striking psychological difference—between the man with acute bronchitis and the man in acute mania? Surely it is that the first man

* A sister of Case 36 † Sister of Case 32
‡ Sister of Case 45 ‖ Sister of Case 44

The term vesicle is retained throughout whatever its contents—i e , serous, sero purulent, or purulent The subcrust exudate (S E) is the exudate found after complete removal of the crusts Staph. = Staphylococcus Strep = Streptococcus Diph. = Diphtheroid. Glyc = Glycerine

TABLE II —*Analysis of Cases*

Organisms isolated	Material obtained from—		Total.
	Vesicle	Subcrust exudate	
Pure strep	10	3	13
Pure staph	9	12	21
Mixed strep and staphy	10	18	28
Pure diph	1	—	1
Mixed strep , staph , and diph	—	2	2
Mixed staph and diph	—	1	1
Totals	30	36	66

Total number of cases	56
Total number of lesions examined	66

Strep found	43 times (in pure culture 13 times)
Staph ”	52 ” (” ” 21 ,)
Diphtheroid found	3 , (” ” once)

In the vesicles pure streptococci, pure staphylococci, and mixed streptococci and staphylococci were found equally often , but in the exudate beneath the crusts the proportion of streptococci to staphylococci was 2 3 In four instances, not recorded above, the cultures from vesicles were sterile (two of these were from Cases 51 and 53)

It is worthy of note that on comparison of the cases (Nos 4, 16, 23, 47, 52, 56) where both vesicle and subcrust exudate from the same case were examined on the same day, it will be seen that in no single instance were staphylococci found in a vesicle when streptococci and staphylococci were present in the subcrust exudate In Cases Nos 41. 42, 44, 45, 46, 47, 51, 54, the skin was tested for the presence of organisms In Cases 44, 45, the cultures were sterile. In the other thing, its methods are so totally opposed to the world of reality that for practical purposes it can of itself do nothing real, obvious, and apparent, except *via* the conscious mind, and we know that its function is to activate, bully, persuade, urge, or humbug the conscious mind into carrying its desires into practical effect Can you imagine what the state of things would be if the unconscious mind in some strange and wonderful way threw off the shackles of the conscious more or less completely, not for an hour or two, but for days, months, or years at a time ? Life would surely correspond with greater or less completeness to a dream, a fairy tale, or a hysterical fugue, to name fleeting or artificially produced states which give a vague idea of what one is after.

Imagine an electric current passing up a wire to activate a number of engines, lamps, and so forth, and returning, of course, by another wire Now this current can only manifest itself against resistance, and the only evidence that it is doing any work at all is to be seen in the glow of the lamps and the activity of the engines A hundred and one things may happen among these lamps and engines which will be abnormal, which will need attention, but which cannot possibly be said to impair the integrity of the system either seriously or permanently The current may vary in strength, loose connexions may spark or flicker, the detailed machinery of the engines may require adjustment, the filament of a lamp may break or burn out, but none of these are beyond repair, and we know from abundant other evidence that the current is still there But suppose that the lead and return wires come into contact and form a short circuit, cutting out the entire collection of machinery which will remain in darkness and silence For all practical purposes nothing seems to be happening. You would be inclined to assume that there is no current there at all, but there is; there is the very same current, only it is not working against any resistance It has become detached from the material which it can activate and make to work, and glow, and live I cannot push that analogy further and I cannot completely connect it with what I have already said, nor with all I think It is the best I can do, however, on this very mysterious matter

In some way which we may not elucidate clearly for many and many a year, I believe that the flickering lamps, the variable current, the loose connexions, are the neuroses, with the light and the movement (that is to say, the supremacy of the conscious mind, the hold on reality), impaired, but present, while the short-circuited system corresponds to the psychoses The machine cannot work, the design is faulty from the very laying of the cables , the current, indeed, is running, but because of the very absence of resistance it gives no evidence of its activity. By throwing off all resistance, by freeing itself from the workaday channels of self-expression, it has only succeeded (as, by the way, many a modern poet and artist has done) in robbing itself of any intelligible means of self-expression at all The work it does is totally unsuited for the needs of any electrical machine, it is, in fact, wasting itself in ways past finding out

CONCLUSION.

The subject under discussion bears directly upon a matter about which we are hearing a great deal of rather wild and woolly talk nowadays—namely, the early treatment of insanity, or rather the treatment of " incipient insanity " The matter is one of immense importance, but if anything has emerged from what I have been saying, it is surely this that whether or no the road from sanity to insanity be a long and slow one, it certainly does not pass through a neurosis Whatever the borderline case about which so much is written may be, it is not, in one case in ten thousand, a person who is wavering between a neurosis and a psychosis

HEXHAM WAR MEMORIAL HOSPITAL—An open-air children's ward has been added to this institution in memory of the late Rev J E McVitie, who was one of its most devoted workers.

AN INVESTIGATION INTO THE ÆTIOLOGY OF IMPETIGO CONTAGIOSA

(56 CASES) WITH NOTES ON TREATMENT (263 CASES)

BY A R BALMAIN, M B , B S LOND ,
D P H.OXF ,

LATE ASSISTANT MEDICAL OFFICER, COUNTY BOROUGH
OF BIRKENHEAD

THIS investigation was undertaken (1) to ascertain the types of organisms usually found in the lesions of impetigo contagiosa , and (2) to discover a remedy which would be antiseptic ; be suitable to remove the crusts , and would heal the lesions of this disease

Historical Summary

Tilbury Fox [1] described this disease in 1864 Crocker [2] (1881) demonstrated that the disease was due to the presence of cocci Two years later Unna stated that it was caused by short-chained cocci Sabouraud [3] (1901) stated that the impetigo of Tilbury Fox was due to the streptococcus, and that secondary infection occurred by the *Staphylococcus pyogenes* Dubreuilh and Brandeis[4] were not able to confirm the dictum of Sabouraud that all types beginning with a vesicle are due to streptococci In eight cases streptococci and staphylococci were found equally often They stated that the clinical aspect of the lesion gives no indication of the bacteriological content

Farley and Knowles[5] in 30 cases found streptococci in 24 cases (10 cases in pure culture), staphylococci 22 times in 16 cases (with other organisms) They consider the streptococcus to be the cause of the disease Smith and Burkey [6] in nine cases found streptococci (pure) in six cases, staphylococci (pure) in three cases They mention the possibility of the action of an unknown virus, and are inconclusive as to the primary cause

The history of the disease appears to leave serious doubt as to the primary cause of impetigo contagiosa

Ætiology

Material —The material for laboratory investigation was obtained from children attending the school clinic for treatment who were suffering from typical clinical lesions of impetigo contagiosa

As all cases (with one exception) came for treatment with the crusting stage already present, it was considered advisable not only to examine vesicles, but also the exudate beneath the crusts, as this investigation was undertaken primarily to deal with the *treatment* of the condition.

Method —Vesicles, after swabbing with ether, were incised with a sharp platinum spud, and a small platinum loop was inoculated Both spud and loop were at once stroked across blood-agar plates In three instances sterile capillary tubes were used The exudate from beneath the crusts was obtained by lifting off the crust with sterile forceps, taking a loopful from the centre of the exudate, and then stroking a blood-agar plate The sterility of these methods was confirmed in the experiments described in Table III

Media and Stains —The medium used was blood agar poured into plates The nutrient agar was lemco peptone salt agar Subcultures were made in all cases where necessary to obtain pure cultures on blood agar or Löffler's blood serum. Stains used for smears were Gram and borax methylene-blue It will be noticed in Table I that hæmolysis was variable Too much emphasis should not be laid on this fact as different blood samples were used in the preparation of successive batches No attempt was made to differentiate the types of streptococci (the two types usually found are stated by other writers to be *Streptococcus pyogenes* and *Streptococcus anginosus*) is a troublesome procedure if used at home often improperly made, and will tend to spread the disease Norman Walker[7] Olive oil is undoubtedly useful Hot water spreads the disease An excellent idea is the use of kerosene, advocated by Whitfield[8] Unfortunately in children there is the danger of fire MacKenna[9] states that it is necessary to produce desiccation or breaking up the crusts and advises the use of a lotion of calamine and sulphur The one method which is quite futile is the application of ointment on the top of the crusts, the cases drag on week after week, and in the end recourse is usually made to that barbarous method, mechanical removal.

The aim of this investigation has been to find a preparation which will remove the ordinary crusts within 24–48 hours, and be an efficient antiseptic against the organisms found in the lesions The following methods were tried in sequence. (1) Ointments (unguentum hydrargyri oxidi flavi 1 per cent and unguentum hydrargyri ammoniati); these are useless (2) Acriflavine 1/1000 with glycerine 50 per cent caused increase in the exudation (3) Acriflavine 1/1000 in castor oil, this softens the crusts, but is slow in action and will not heal the lesion (4) Acriflavine 1/1000 in paraffin emulsion, effective and antiseptic

In the preliminary use of this emulsion it was made up according to Martindale's formula, but, finally the emulsion, made according to Stowell's formula* was chosen[10] This contains —

Acriflavin. hydrochlorid	0 1
Liquid paraffin .	76
White wax	4
Water	20

Action of Acriflavine 1/1000 in Paraffin Emulsion — The paraffin causes breaking up of the crusts which come away on the dressing without force, in 24–48 hours in most cases In others a further application is required (in dealing with old black crusts a preliminary starch poultice is indicated)

The properties of acriflavine, which is diaminomethylacridine chloride, as an efficient antiseptic are well known (Browning, Kennaway and Thornton)[11] It is 20 times more powerful than mercuric chloride, and acts well in the presence of serum (an important factor in this disease) Gray[12] has recommended the use of lotio acriflavini 1/1000 in the bullous type of the disease

Method of Use —Lint was well soaked in the acriflavine emulsion, and bandaged or strapped over the affected area (any vesicles present were first opened)

The next problem was the after-treatment of the lesions In my opinion the best and quickest results are obtained by continuing the dressings with acriflavine emulsion Where this is done, the lesion heals rapidly, cases have been cured in two to three days The worst cases, of course, take longer Trials of various ointments have been made, including hydrarg ammoniat 1 per cent, 2 per cent, and 3 per cent, hydrarg ox flav ½ per cent., 1 per cent, and 2 per cent (with and without zinc oxid), made up with a vaseline or soft paraffin base Compared to the acriflavine emulsion dressing, the use of ointments seems to me to be unsatisfactory

Cases (Treatment of cases since the commencement of the investigation in May, 1925)

Total* number of cases treated with acriflavine 1/1000 in paraffin emulsion	201
Total number of cases treated with other acriflavine compounds	30
Total number of cases treated with other methods ointments, &c	32
Total by all methods	263

* Some of these cases were ordered ointment after they had been dressed twice with acriflavine emulsion.

Conclusions

1 In a series of 56 cases examined streptococci were found 43 times (13 times in pure culture); staphylococci were found 52 times (21 times in pure culture), diphtheroids were found three times (once in pure culture) 2 Vesicles, whether serous or purulent, and the exudate beneath the crusts may contain the streptococcus 3 The majority of cases are infected with streptococcus plus staphylococcus 4 Human experiments prove that the streptococcus will produce typical lesions of impetigo contagiosa 5 It is considered that the most suitable treatment for impetigo contagiosa, both for removal of the crusts and the healing of the lesion, is with acriflavine 1/1000 in paraffin emulsion.

I should like to acknowledge the great debt I owe to my colleague, Dr H. Mason Leete, for his supervision and suggestions, especially with regard to the technique of obtaining material from cases, skin tests, human experiments, media making, and bacteriological controls His kind help and advice have made this research possible Also to thank Dr D Morley Mathieson (medical officer of health, Birkenhead) for his kind permission to undertake the work.

AN OPERATION FOR CREATING AN ABDOMINAL "SHELF" IN CERTAIN CASES OF VISCEROPTOSIS IN WOMEN.

BY VICTOR BONNEY, M S, M D, B Sc LOND, F R C S. ENG,
SURGEON, CHELSEA HOSPITAL FOR WOMEN, ASSISTANT GYNÆCOLOGICAL SURGEON, MIDDLESEX HOSPITAL.

THAT visceroptosis is far commoner in women than in men is due to several causes The whole substance of the abdominal parietes is everywhere much less strong and resistant in the female than in the male, and particularly in that portion which bounds the inferior limits of the peritoneal cavity—namely, the pelvic floor and the other tissues which close in the pelvic outlet This weakness in the woman as compared with man is related to the function of child-bearing and childbirth, which would be interfered with if the abdominal cavity were bounded by structures of any considerable rigidity. Nature, however, in her concern to secure the best possible conditions for the growth and delivery of the child has, as regards the mother, "cut it so fine" that more or less laxity often remains after the labour, and the woman suffers permanently from some variety of visceral displacement The elasticity of the tissues varies immensely in different women, and in different parts of the same woman In one, for instance, a single pregnancy will leave the abdominal wall like crinkled paper, whilst in another a dozen will scarcely leave a mark. Some fortunate persons, but very few, are made of first-class material throughout, others are mostly made of shoddy, almost all have some shoddy somewhere in their make-up.

In addition to pregnancy and childbirth women are subject to conditions of malnutrition, with consequent tissue weakness, almost peculiar to their sex, the causation of which is at present obscure. Such cases all types (aureus, albus and citreus) of *Staphylococcus pyogenes* were found; the streptococcus was absent The method used was to scarify lightly with the platinum spud a clear area of skin on the cheek, place a drop of sterile saline on the area, and inoculate the culture medium with the platinum loop or spud

---

* Originally produced by Mr Humphreys, chemist, of Norwich. It is a stable emulsion

Other Factors —Of other factors in the ætiology, sex and age of children appear to have no bearing on the disease (in one family the mother was infected on the face and breasts from the baby, and then the two elder children contracted it) Both clean and dirty children contracted it by contact; others by a dirty abrasion, and some following scratching in scabies or with nits in the scalp In 100 consecutive cases malnutrition or anæmia was recorded as present in 25 instances Otorrhœa was present in Cases 16 and 56

Experiments on Adult Skin

The experiments were performed on the writer's forearms, with the exception of Nos 5 and 6, in which Dr. H Mason Leete was inoculated Seven of these experiments were with exudates direct from other lesions, the other five were inoculations with living subcultures on blood-agar plates taken from actual cases of impetigo contagiosa (Table III)

Skin Tests —These were made in six instances from the skin of the forearm, one culture showed the presence of *Staphylococcus citreus*, the others showed no growth

Expt 2 —Twenty colonies were inoculated The lesions resembled typical impetigo contagiosa. The formation of the crusting stage was watched and the crusts were seen to be due to the drying up of the exudated serum The direct smears from the bulla showed many leucocytes, diplococci, streptococcal chains (four elements)

Expts 1, 3, 4, 5, 6, 9, 12 —It is suggested that the dosage of organisms inoculated was insufficient to overcome the skin resistance

Table III —Experiments

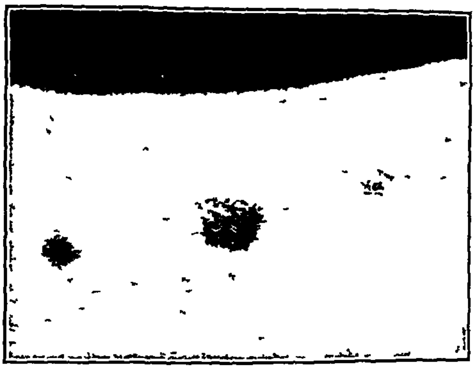
No	Date in 1925	Organisms inoculated	Lesion produced.	Time	Organisms recovered	Method of inoculation
1	30/9	Exudate from Case 41 (staph)	Slight erythema Fading	24 hours 48 "	Nil	Direct rubbing, small area
2	24/10	Strep from Case 47 vesicle, second sub	Vesicle Turbid bulla Crusts Clinical lesions of impetigo contagiosa	24 " 48 " 50 "	Strep in pure culture	Sc Massive dose, area ½ inch.
3	26/10	Exudate from Expt 2 bulla	Slight erythema	24 "	Nil	Light sc
4	26/10	" "	Nil	24 "	Nil	Rubbing
5	26/10	" "	Nil	24 "	Nil	Light sc
6	26/10	" "	Nil	24 "	Nil	Rubbing
7	30/10	Staph from Case 48 vesicle, first sub	Turbid vesicle Purulent bulla " " "Healing" No crust formation	24 " 48 " 56 " 80 "	Staph pyog aureus in pure culture	Sc. Massive dose, area ¼ inch
8	30/10	Staph from Case 48 vesicle	Erythema Fading	24 " 48 "	Nil.	Sc Mod dose
9	2/11	Exudate from Expt 7 bulla	Erythema " Fading	24 " 48 " 56 "	Nil	Sc.
10*a*	26/11	Strep from Case 55 vesicle, first sub plus staph from Case 52 vesicle, second sub	Turbid vesicle and erythema Bulla. Crusts	24 " 48 "	Strep and Staph pyog aureus	Sc Dose (approx) strep 1, staph 4 Area ¼ inch
10*b*	2/12	—	Exudate.	5 days	Strep and Staph pyog aureus	—
11	26/11	Staph from Case 52 vesicle, second sub	Erythema Fading	24 hours 48 "	Nil	Sc Small area
12	28/11	Exudate from Expt 10*a* bulla	Nil.	—	Nil	*Light sc*

Sc. = Scarification

Expt 7 —A loopful of culture from a blood-agar plate was inoculated Although a purulent bulla was formed with surrounding erythema, on removal of the roof of the lesion and evacuation of the exudate no crust formation occurred, but the lesion commenced to dry up immediately (compare Expt 2)

Expts 8 and 11 —The skin resistance was too great for the organisms

Expt 10 —The inoculation was approximately four times as heavy with staphylococci as with streptococci. A typical lesion of impetigo contagiosa was produced, crust formation occurred The direct smear from the vesicle (which was turbid) showed leucocytes, many diplococci, some streptococci (with four elements), and a few staphylococci The subcultures showed a mixed streptococcal and staphylococcal infection The organisms were isolated on second subculture Five days after the inoculation, cultures from the exudate showed mixed streptococci and staphylococci (an interesting point was that the streptococci grew well on a plain agar plate)



Writer's forearm Experiment No 7 Turbid vesicles coalescing to form a purulent bulla after 48 hours, resulting from inoculation with staphylococci.

Inferences Drawn from these Experiments

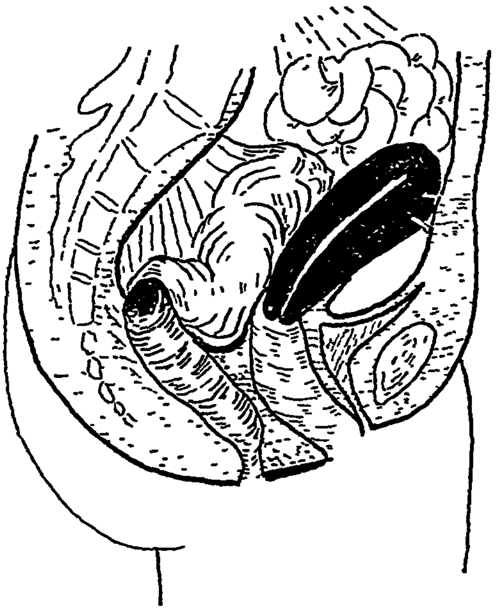
(1) The streptococcus will produce, in the adult, lesions identical with those of impetigo contagiosa (2) Crust formation is due to drying of the exuded serum Staphylococci are not necessary for the formation of crusts (3) The normal adult human epidermis may be resistant to infection with *Staphylococcus pyogenes* (unless a very massive infection) (4) The inoculation of streptococci plus staphylococci cultured from cases of impetigo contagiosa leads to the following result (*a*) formation of a *true* impetigo lesion, (*b*) symbiotic growth of both organisms in the lesion

Treatment

The treatment of impetigo contagiosa resolves itself into two parts (1) before and (2) after removal of the crusts

The methods which have been advocated in the past for the removal of the crusts are the starch poultice, olive oil, hot water, kerosene, desiccation with lotions, ointments, mechanical removal with forceps *The starch poultice is very effective, but it* cavity, and then, still keeping the forceps subperitoneal, inwards under the peritoneum just in front of the ligament, until the forceps point reaches the situation where the pleating suture has been tied. The forceps point is then thrust through the peritoneum, the long ends of the pleating suture are seized, and the forceps are withdrawn the way they came, bringing the ends of the suture with them.

FIG 3



Showing how the "shelf" alters the position of the intestines

Traction on these sutures pulls the pleated part of the round ligaments against the abdominal wall to which they are subsequently fixed by passing the two ends of each suture through the aponeurosis on either side and tying them there This is the method of round-ligament shortening that I now employ, as it effects a stronger suspension of the uterus than the older method in which merely loops of the ligaments were employed. The method leaves no gap through which intestine might make its way between the attached part of the ligaments and the lateral abdominal wall The uterus itself has now to be attached, and this is effected by passing two silk sutures through the upper part of its anterior wall, which also pass through the aponeurosis and peritoneum on either side of the wound Before, however, tying these sutures, it is necessary to pass a mattress suture lateral to them on either side, which, taking off from the uterus in the interval between the ventrofixing sutures and the pleated ligament, perforates the peritoneum and aponeurosis some half an inch outside their cut edges, and is tied there The object of these sutures is to close the gap, which would otherwise exist, between the points where the uterus is ventrofixed and the round ligaments are attached The wound is then closed in the usual way.

The technique described results in the formation by the uterus and broad ligaments of a partition running transversely across the abdominal cavity, entirely separating it from the utero-vesical space (Fig 2) This partition in the standing posture forms a shelf on which the intestines rest Moreover, the front portion of the abdominal cavity is shortened by some three inches, so that the drag on the mesenteries is diminished by that amount, whilst the intestinal pressure is directed downwards and backwards into an opened Douglas's pouch (Fig 3) I have been performing this operation for some years with successful results, and all the patients on whom I have carried it out have been materially benefited by it I therefore commend it to other surgeons as worthy of a trial Care should be taken to fix the uterus sufficiently high to give the bladder ample room, and silk should be used for the main fixation sutures

I have no actual experience of the effect of the operation on subsequent pregnancy, as none of my patients have conceived, most of them having been of an age when pregnancy was unlikely. Judging, however, from the fact that neither ventrofixation, when properly performed, nor round-ligament shortening have any ill-effect on pregnancy or labour, I believe that this operation, which combines the effect of the two will be equally harmless In a good many of the patients of the type under discussion the visceroptosis is entirely due to repeated child-bearing, and in such it is proper to tie the tubes and prevent further pregnancy.

There are certain variations in the technique of the operation applicable to special cases which should be mentioned The combination of symptoms of enteroptosis with menorrhagia either due to fibroids or uterine fibrosis is not uncommon. In such cases, if we cure the menorrhagia by hysterectomy, we make the enteroptosis worse, for a new space of considerable dimensions is created, into which the intestines, already prolapsed, will prolapse further. It is not, however, necessary, as a rule, to remove the uterus. In the case of fibroids the tumours should be enucleated and the sutured uterus used to make the "shelf" in the manner described. This is the more desirable because after myomectomy suture of the uterus to the abdominal wall along the line of the incision in the uterus (which should be on its anterior wall) is good technique, as it safeguards against oozing from the uterine wound When the bleeding is due to fibrosis there are no discrete tumours to enucleate, but even here removal of the organ can be avoided, for through an incision in its anterior wall all the endometrium can be excised, and when the uterus is sutured it becomes a solid column of muscle without any cavity left to bleed from, and this solid column can be ventrofixed to form the centre part of the shelf.

When the cæcum is markedly prolapsed I suture its caput to the back of the right broad ligament which forms the right-hand portion of the shelf, so as to prevent this portion of the bowel sinking into the pelvis. Similarly the pelvic colon can be sutured to the back of the left broad ligament, if there seems any advantage in so doing

HAY FEVER

BY F G. CHANDLER, M D CAMB., F.R C P LOND.,
PHYSICIAN WITH CHARGE OF OUT-PATIENTS, CHARING CROSS HOSPITAL PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS

IT is a curious fact that although many hay fever subjects may react most strongly to the pollen of *Phleum pratense* (Timothy grass)—that is to say out of those limited numbers of pollens usually employed—their hay fever will begin many weeks, often two months, before the Timothy grass comes into flower. Moreover, in many parts of the country this grass is comparatively rare One may walk for miles without seeing a single specimen It is clear, therefore, that hay fever is not caused by Timothy grass pollen Freeman,[1] however, denies to the toxin any specificity Any pollen, he says, may produce the same reaction, but in a lesser degree A mixed antigen, therefore, is not necessary, and an attempt to produce a specific antigen is in vain; and for treatment all that is necessary is a Timothy grass pollen antigen I doubt if this hypothesis is tenable. It is true that most hay fever subjects will react to Timothy grass, and that the reaction to this pollen is frequently the most marked Nevertheless, if tests are made of various pollens (and I think the dermal method is by far the best method of making the test),[2] it will be found that a marked reaction is aroused by some grasses and none by others For example, a certain case (D F) tested by the following grasses gave the following results —

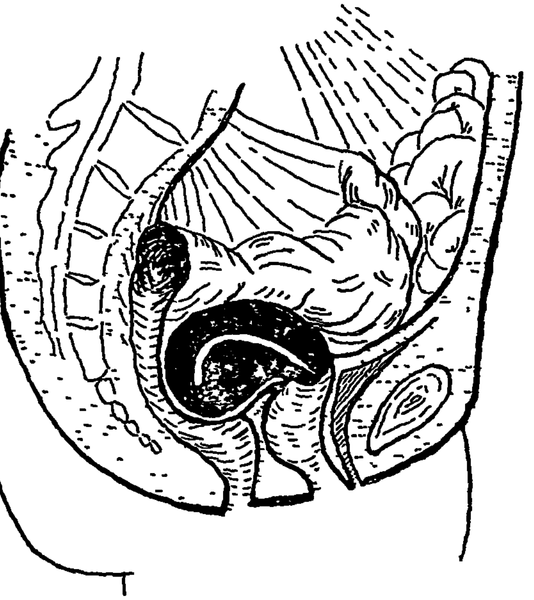
---

[1] Freeman J THE LANCET 1911 ii 814
[2] Chandler, F G THE LANCET, 1925, i, 1177

patients present a characteristic picture, being thin and angular in appearance, with pigmented, harsh-looking skins and bluish-red cold hands They look as though "their food didn't nourish them," to use a popular lay phrase. Many of these women have visceroptosis, although they have never borne children

There is much variation as to which organ or group of organs takes part in a visceroptosis. In some cases the kidneys, transverse colon, and stomach are more particularly affected, in others it is the uterus, vagina, and pelvic colon and cæcum, whilst in others again all the organs lying in the abdomino-pelvic cavity droop It is with the last two of these groups that this paper is concerned, because in both of them retroversion of the uterus is usually present, and often some variety of prolapse as well, and as a result the symptoms are chiefly pelvic or lower abdominal, and the gynæcologist sees a large proportion of these patients The symptoms complained of are a sense of weakness preventing any prolonged exertion, backache, and pain referred to the lateral parts of the lower abdomen, in the region of the appendix and cæcum on the right side, and the point where the colon crosses the pelvic brim on the left side This pain, which is evoked by standing and exertion, and which disappears with recumbency, is probably due to drag on the ovario-pelvic ligaments. When the supporting apparatus of the vagina (the cardinal ligaments and levator diaphragm) partakes in the ptosis, the symptoms of prolapse are also present—namely, bearing-down pain and a sense of something falling In addition, there is present in most cases more or less evidence of intestinal toxæmia, secondary to intestinal stasis, indigestion, flatulence, obstinate constipation, and general ill-being In a paper by myself and Moreland McCrea, published in THE LANCET of Nov 10th, 1923, we pointed out that retroversion tended to produce constipation, chiefly because the backwardly-lying uterus interfered with the natural function of Douglas's pouch We showed that this extension downwards of the peritoneal cavity plays an important part in the mechanism of defæcation because it permits pressure to be brought to bear on the upper rectum by the intestinal coils forced into the pouch during the act of straining. All conditions which obliterate or fill up Douglas's pouch are accompanied by constipation, excepting those (such as acute inflammatory masses) which actively irritate the bowel When the retroverted uterus is large enough it hampers free passage through the bowel by sheer pressure, but the chief ill-effect of this displacement arises from the fact that when Douglas's pouch is filled up by the uterus the intestinal coils during straining or any act that raises the intraperitoneal pressure are forced forwards above and in front of the uterus, and their compressional effect is exercised not as it should be, on the rectum, but on the bladder, and through it on the anterior vaginal wall Such a change in the direction of the compressional force tends to cystocele

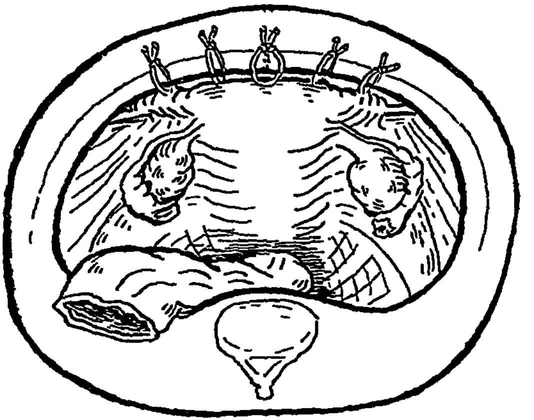
FIG 1



Showing the position taken up by the intestines when the uterus is retroverted

A further effect is that the absence of the uterus from its normal position leaves a considerable free space between it and the bladder into which the pelvic colon prolapses forwards, with the result that the meso-colon becomes elongated, whilst the lower coils of the small intestine descend into it, with a corresponding elongation of the mesentery, and these elongations are enhanced by the chronic distension of the intestine which accompanies the stasis (Fig 1) A large proportion of the cases of the type I have described come up for treatment and are operated on primarily on account of the genital displacements I thus came to notice that operative rectification of a retroverted uterus, either by ventrofixation or round-ligament shortening, was frequently followed, not only by disappearance of the symptoms strictly due to the retroversion, but also by great improvement in the symptoms ascribable to the intestinal ptosis The reason for this, I believe, is not only that the operation restores the normal defæcatory mechanism and sometimes removes a hampering pressure from the lower bowel, but also because the replacement of the uterus shortens the abdominal cavity in its lower and front part, so that the intestines cannot fall so far in that direction, because the uterus and broad ligaments occupy the space where they would fall I therefore began in selected cases to fix the uterus and broad ligaments in such a way as to form a complete barrier across the front part of the lower abdomen, completely cutting off the utero-vesical pouch from the general peritoneal cavity The operation is in effect a combination of the operations of direct ventrofixation and round-ligament shortening, and is carried out as follows

FIG. 2.



Showing the "shelf" and the sutures that hold it in position

Technique of the Operation

The abdomen having been opened the round ligaments are pulled up and a puckering suture is run along each, starting about an inch from the point where the ligament leaves the abdominal cavity and ending at the attachment of the ligament to the uterus This suture, when tied, pleats the part of the ligament sutured, so that it forms a solid excrescence, attached to the side of the uterus, which is presently used to suspend that organ The suture should be passed through the ligament itself, not merely through the peritoneum covering it, and the tied ends are left long Starting from the edge of the wound, the round ligament forceps are passed outwards between the abdominal aponeurosis and the rectus muscle until their point reache the spot where the round ligament leaves the abdomina is clamped and the two placed in position for anastomosis Not infrequently the first inch or more of the jejunum is attached to the under surface of the mesocolon by a membrane triangular in shape and varying in breadth, and this must be divided before putting on the clamp

It is very important that the edges of the opening in the mesocolon should be sutured to the stomach wall after the anastomosis is completed, because, apart from anything else, when the clamps are removed the stomach readjusts itself and recedes into the lesser sac, and if its lowest part lies to the right of the midcolic artery it will drag a part of the bowel lying just distal to the anastomosis with it, and kinking will ensue owing to its being slung over the right edge of the mesocolic opening in which runs the artery

Advantages of the Method

The advantages of this method are · (1) That there is a vertical or slightly oblique opening in the posterior wall of the stomach extending right into the great curvature at its most dependent part (2) That there is very little disturbance of the normal anatomical relationship of stomach and proximal jejunum, the factor of relationship being an extremely important one in any operation (3) That the anastomosis is, for all practical purposes a natural no-loop one. (4) That the incision is placed between the large vessels which run upwards for a variable distance on the posterior surface of the stomach If any of these should, however, be cut, the hæmostatic stitches whose direction is necessarily at right angles to them, are very efficient in checking hæmorrhage (5) That in the matter of drainage an incision into the lowest part of the stomach is more effective than one placed elsewhere. (6) That no matter what shape or form the stomach may assume during contraction, the food must in its passage onwards reach that opening (7) That there is never any regurgitant vomiting, immediate or remote

I am well aware of the fact that many surgeons use a vertical incision into the stomach, but what I have tried to emphasise is that there are several very important factors which have a distinct bearing on the length, direction, and position of that incision

There is another incision commonly used—the transverse or oblique This lies horizontally between the two curvatures of the stomach and must inevitably involve a certain amount of kinking of the jejunum both at its commencement and at the stoma in a no-loop, and at the stoma alone in a short-loop operation The nearer the greater curvature this incision is placed, the greater the danger from hæmorrhage The anatomical relations of the parts are unnecessarily disturbed The stoma does not under any circumstances lie at the most dependent part of the stomach Even when the stomach is full there is a quantity of food which will pass on towards the pylorus without ever having the opportunity of coming into contact with the opening, and this is the portion of food which passes below the level of the stoma and makes its way out through the pylorus

I have on many occasions observed this on the X ray screen, and in order to lessen this possibility and increase the facilities for drainage I devised an operation [1] which I have since given up in favour of the method dealt with in this note Believing, as I do that drainage is of prime importance I feel quite sure that this method is the most suitable and satisfactory from every point of view, and that no other is so efficient

---

EAST LONDON HOSPITAL FOR CHILDREN,
SHADWELL.

A primary consideration in attempting to assess the result of any diseased process is an estimation of the degree to which repair is possible No single factor is more concerned in this than is adequacy of circulation Absence or deficiency of oxygen or food will prevent recovery when all active toxæmia or infection has ceased It is not enough to regard the larger vascular supply for the smallest arterioles and capillaries are the only intimate intermediaries between the lymphatics and parenchyma of the organ and its food sources

The object of this paper is to analyse the dependence between cardiac function and cardiac circulation The conclusions in it are manifestly incapable of experimental proof in the human subject but some of them are necessarily true upon logical and physiological grounds alone Almost without exception the causes of heart failure are primarily poisons Some, like that of diphtheria, are exotoxins and produced away from the heart; others, like that of syphilis and possibly also of rheumatism arise from a local infection When the poisons themselves have been neutralised or have ceased, recovery should occur provided the blood-supply to the parenchyma is efficient An anatomical examination of the vascular system of the heart is incapable of suggesting, as does the portal or pulmonary, its essential variations from the normal It has arteries capillaries, and veins as has any other organ, but differs from all others in its rhythmic motility

Physiologically, it is an easy matter to measure the outflow from the coronary sinus, to deduce from it the amount of the coronary flow and to measure the volumetric changes produced in this by a number of different factors A measurement of the flow as it occurs in the lumen of the coronary arteries during systole and diastole and the relation of this to the various phases of the cardiac cycle, is a different matter, for allowance must be made for the effect of the peripheral pressure exerted upon the terminal distributions deep in the substance of the contracting muscle The vessels must, therefore be thought of anatomically in reference to this effect upon them of cardiac function Contraction of the heart will completely empty the capillaries and veins and will prevent the entrance into the substance of the organ of arterial blood during systole, for the systolic arterial blood pressure, at any rate in the all-important left ventricle must be equalled by the systolic muscular force, and peripheral arterial pressure decreases with the diminution in the size of the lumen

Tracings of intra-coronary pressure taken physiologically show a systolic rise that is maintained also to some degree during diastole, but such tracings are apt to give a false mental picture Similar tracings of the systemic circulation taken from the radial pulse are accompanied by a concomitant onrush of arterial blood through the organs, and an unreflecting examination of coronary tracings by analogy accepts a similar result in reference to the heart Reflection will show that both are pressure readings and that the coronary systolic period is accompanied by no corresponding flow through the contracted heart muscle The surface arteries only are filled with blood at the systolic pressure, but this blood is for the moment relatively stationary and prevented by muscle contraction from entering the vessels in the substance of the organ This preliminary filling of the surface vessels can have no relation to the nutritive flow through the substance of the heart, and in the argument it is therefore disregarded, attention being confined to the latter essential process Thus, the individual heart muscle-fibres receive through their nutrient

Table showing Reaction to Certain Grasses

—	Grasses	—	Wheal (cm)	Red zone (cm)
1	Mixed grass pollen (Duncan, Flockhart)	+ + +	2 ×1	5 ×3
2	Foxtail grass (*Alopecurus*)	0	0	0
3	Rye grass (*Lolium*)	+	0 6 ×0 6	2 5 ×2 5
4	Meadow grass (*Poa*)	0	0	0
5	Yorkshire fog grass (*Holcus*)	+ + +	1 ×1	3 ×5
6	Cock's foot grass (*Dactylis*)	0	0	0
7	Timothy grass (*Phleum*)	+ + +	2 ×2 2	7 ×4

Again in a case (W W B) I found no reaction to Timothy grass, but a marked reaction to *Lolium* and *Holcus*

There would appear, therefore, to be several pollen toxins and not one pollen toxin. If this is so it would seem reasonable to attempt to make a more specific antigen and not to use Timothy grass pollen as a more or less non-specific desensitiser This I have been doing in my own practice for the last year or two with apparently good results

What is the Exciting Cause ?

Seeing that Timothy grass pollen is not responsible for the onset of hay fever, it is a matter of great interest to know what is the exciting cause Now it is the anemophilous plants alone that are likely to cause this disorder Of these the most important are certain trees, the flowering trees and the catkin trees (*Amentaceæ*), sedges, rushes, and grasses I have tested several tree pollens but have seldom obtained a reaction Most of the sedges and rushes come into full flower after the beginning of the hay fever season Of the grasses the most common early flowering grass is *Anthoxanthum odoratum* (sweet-scented vernal grass), whole acres of which may be seen fully out in May This spring I have collected the pollen of this grass, and with it suspended in 14 per cent alcohol I have obtained very marked and intense dermal reactions, so great as to leave little doubt that this is one great cause at least of hay fever, if not the chief cause

Of those cases that I have been able to test up to now very marked reactions have been obtained, e g

Case	Wheal (cm)	Red zone (cm)
D F	2 ×2	4 ×4
H C	2 ×1 5	5 ×3
G H B	1 75 ×1	4 ×4
E R	4 ×3	6 ×5
F M	1 5 ×1	3 ×3
C G	2 ×1 5	4 ×4

Theoretically, we ought to be able to desensitise pollen-sensitive subjects Sometimes we seem to succeed, at others to fail I believe that frequent injections are necessary, at least three injections a week, immediately before and during May, and then at perhaps longer intervals for the rest of the hay fever season I would suggest that Anthoxanthum pollen should be added to the usual group of test pollens, and that this should form a constituent of all stock hay fever vaccines If a pretty name is required, Anthoxanthene might meet the demand The pollen may be collected by taking the heads, just before the anthers are due to emerge from the glumes, and grinding them up with 14 per cent alcohol and straining off all coarse particles; or the grass may be collected just before flowering, placed in water, protected from draught, and the pollen allowed to fall upon paper In sheltered positions it is possible to collect the pollen from the grass where it grows direct; but usually all the pollen grains are blown from the anthers the very moment they ripen

I suggest that a method of scientific standardisation of the solutions of the pollen would be to count the grains, as leucocytes are counted, and subsequently to dilute and treat as may be needed

Anthoxanthum pollen solutions may now be obtained from Messrs Duncan and Flockhart

SOME ANATOMICAL AND MECHANICAL FACTORS TO BE CONSIDERED IN THE OPERATION OF POSTERIOR GASTRO-JEJUNOSTOMY

By DONALD MacLEOD, F R C S Edin ,
HON SURGEON, LEIGH INFIRMARY, LATE R S O , NORFOLK AND NORWICH HOSPITAL

Posterior gastro-jejunostomy is admittedly the operation of choice in the treatment of duodenal ulcer, but the method varies and the function is still in dispute There are two schools, one of which believes that the physiological effect is the predominant factor, the other that drainage of the stomach is the mainly important one I believe that this operation is essentially one of drainage, and where no-loop gastro-enterostomy is used as a drainage operation there are definite indications for the length, direction, and position of the incision into the stomach In view of differences in the technique adopted by different surgeons it may be worth while to review these indications

In a large series of observations made during operations and at other times in the anatomical department of the Victoria University, Manchester, it was found that the position of entry of the jejunum into the general peritoneal cavity—that is, that part of the jejunum which lies below the duodeno-jejunal flexure as it passes either through the transverse mesocolon or immediately between it and the posterior abdominal wall—is constant in position regarding its level, and lies either in front of or to the left side of the third lumbar vertebra In some cases of general visceroptosis it was placed as low as the lower border of the fourth, but it was always well above the level of the greater curvature The position of the lowest part of the stomach is not constant, but lies somewhere on the greater curvature, between two points, one of which lies one inch and a half from the pylorus and the other two inches to the left of the middle line No matter how atonic or hypertonic the stomach, this never varies What appears on mere inspection to be the lowest part of the stomach is not necessarily so, as the position of the pylorus may vary according as the patient is supine or erect The most dependent part of the stomach can be found by pulling the wound edges apart and applying gentle and even traction downwards on the greater curvature itself, or on the transverse colon from left to right or vice versa In the great majority of cases this lies to the left of the midcolic artery, but in a few it is placed to the right

The subjacent proximal jejunum—that is, that portion of the jejunum extending from its point of entry to the point where it is crossed by the greater curvature—runs sharply downwards, in most cases across or just to the right of the most dependent part of the stomach, and in a lesser number of cases slightly obliquely to the left

The length of that portion of the posterior stomach wall lying in relation to this part of the jejunum varies, of course, according to whether the commencement of the jejunum lies nearer the greater or lesser curvature, but in every case there is ample for a no-loop anastomosis with a satisfactorily large stoma

We have here, then, a most tempting method for our anastomosis, and that is to open into the lesser sac through the transverse mesocolon to the left of the middle line, and stretch this opening in all directions—particularly upwards and backwards to the commencement of the jejunum, and downwards as far as the arch of the left branch of the midcolic artery We then note the point on the posterior wall of the stomach which lies in relation to the jejunal entry, and apply our clamp to that part of the stomach lying between this point and its lowest part, the stomach, of course, having been pulled out through the meso-colic opening An equal length of proximal jejunum possibly be influenced by loss of aortic elasticity. Tachycardia above an unknown rate must inevitably impair the cardiac circulation, though this might be to some extent compensated by a raised diastolic pressure. In assessing any cardiac or cardiovascular lesion it is logical to consider separately its possible effect upon the cardiac circulation.

In attempting to devise fresh methods of therapy in cardiac failure or disease the virtues of bradycardia as a definite end to be sought should be borne in mind.

Note.—Since completing the above paper the writer has had the privilege of personal communication with Dr. G. V. Anrep, who has devised an electrical method of measuring coronary flow. A chart indicating the time relations between the systoles of auricle and ventricle with the flow of blood in the coronary arteries and coronary sinus is appended, thanks to his kindness. Dr. Anrep's work is in process of publication and confirms in the main the conclusions reached above.

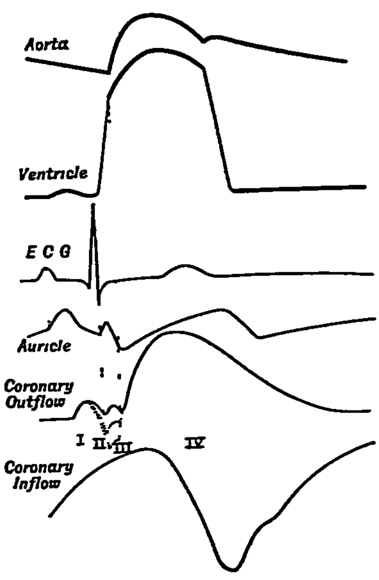

Chart showing time relations between (from top downwards) (1) aortic pressure, (2) left intraventricular pressure, (3) electrocardiogram, (4) intra-auricular pressure, (5) outflow of blood from the coronary sinus, (6) inflow of blood into the coronary arteries. Readings 5 and 6 refer to the ebb and flow of blood in and into the coronary vessels, and the argument in the text refers to the conditions in the smallest vessels in the substance of the muscle. It is suggested that the continued flow of blood into the coronary arteries (not necessarily into the cardiac substance) during the early part of systole may be due to two factors: (1) the distension of the epicardial vessels, (2) the fact that the right intraventricular pressure is less, normally, than is the left, so that the effect of this latter—as manifested by the systolic intra aortic pressure—may be to force some blood into the right ventricular substance against the resistance of the former. The argument as regards the ultimate vessels of the left ventricle—and possibly as regards those of the right—remains unaffected.

LIVERPOOL OPEN-AIR HOSPITAL FOR CHILDREN.—This hospital at Leasowe, in Cheshire, is maintained by grants from the Liverpool Corporation, the Ministry of Health, the Board of Education, and various local authorities. The report of the senior medical officer, Dr. T. Hartley Martin, shows that last year 82.8 per cent. of all cases treated were discharged "disease quiescent"; 26 of the total of 213 discharged were found, after a short stay, to be non tuberculous. Six patients were discharged as unimproved; one of them, a case of tuberculous osteitis, had been in the hospital for 1531 days. Several out-patient clinics have been established, and Leasowe claims to have been the first hospital in the country where after-care work formed part of the original scheme. All the children who are able to benefit receive three and half hours instruction daily.

Clinical and Laboratory Notes.

TWO CASES OF SPLENECTOMY IN PURPURA HÆMORRHAGICA

BY A. W. FALCONER, C.B.E., D.S.O., M.D. ABERD., M.R.C.P. LOND.,
PROFESSOR OF MEDICINE, UNIVERSITY OF CAPE TOWN,
AND
A. R. MCLACHLAN, F.R.C.S. ENG.,
LECTURER IN CLINICAL SURGERY AT THE UNIVERSITY

Kaznelson[1] first published a case of splenectomy in purpura hæmorrhagica in 1916, but it was not until Brill and Rosenthal's paper in 1923 that general attention was called to the operation. Since then many cases have been published. In the great majority of cases of typical purpura hæmorrhagica the results have been very satisfactory. In the more atypical cases the results have been frequently disappointing.

Clinical Records.

The following two cases have been under our charge.

CASE 1.—J. S., female aged 10. Up to the beginning of December, 1923, the child had been perfectly well. She then developed purpuric spots over the thighs and legs. A fortnight later she began to suffer from epistaxis. On Dec. 23rd she was seen by Dr. S. E. Kark. She was running a temperature up to 103° F. There were numerous subcutaneous ecchymoses and petechiæ over the body. Both elbow-joints were painful, fusiform in shape, and the skin over them discoloured. A blood film examined at the Government Pathological Laboratory, Cape Town, reported a secondary anæmia with a normal differential leucocyte count. She was treated with injections of thrombin and calcium lactate by mouth without effect. From Dec. 25th she had an intravenous injection of afenil every second day for six injections. During this period the temperature became normal and the bleeding stopped, but a week later all the symptoms recurred. She then had a whole blood transfusion. Following the transfusion she improved, but three days later she had a very severe attack of epistaxis. The posterior nares were plugged and the septum cauterised. A few days later a profuse hæmaturia occurred. On March 10th she was seen by one of us (A. W. F.) in consultation with Dr. L. F. McDowell. The child was extremely ill, profoundly anæmic, and was running an irregular temperature up to 103°. There were numerous purpuric spots all over the body, epistaxis was continuing in spite of plugging of the nose. There was constant oozing of the gums and an intermittent hæmaturia. The spleen was just palpable. A blood-clot which had stood from the night before showed no attempt at retraction. The bleeding time was much prolonged. A blood film showed intense anæmia with anisocytosis and polychromatophilia, and an occasional normoblast. Blood platelets were much reduced, only an occasional isolated large platelet being found. There were no abnormal white cells.

As bleeding was still continuing freely and the condition of the child seemed critical a blood transfusion followed by splenectomy was advised. On March 11th, 1924, Dr. McLachlan removed the spleen, preceded by a transfusion of 300 c.cm. of citrated blood. For 24 hours the condition of the child was critical, but no further bleeding occurred after the operation. A moderate pyrexia continued for a week, but the temperature then became and remained normal and the child rapidly became convalescent.

Macroscopic description of the spleen.—Weight, 272 g.; measurement 14 × 9 × 3 cm. The surface was smooth and somewhat soft in consistence. Stroma had a reddish appearance, the Malpighian bodies standing out as white dots.

Microscopic description of the spleen (Prof. B. F. Ryrie): The capsule is of normal thickness and the coarse stroma of the organ is not increased. Arteries and arterioles are normal in appearance. The Malpighian bodies are of normal frequency but stand out very prominently on account of their structure. Each shows a relatively large pale centre in which the cells are large and show faintly staining cytoplasm. The nuclei of these cells vary, are large, irregular in shape, and show much karyolysis and karyorrhexis. Frequently these central cells tend to diminish in numbers, arterioles and capillaries no blood whatever during systole. Their intimate supply of oxygen and food is contingent upon diastole and is limited entirely to that part of the cardiac cycle. The effect of systole is to wring out from the organ its waste products and to prepare it for its next diastolic supply.

The cardiac circulation is thus the antithesis of the systemic; it is inverted in point of time. The term "cardiac circulation" should be restricted, functionally speaking, to this diastolic supply of oxygen and food and systolic elimination of waste products. It is in this sense that it is used hereafter.

Factors Influencing the Cardiac Circulation

The systolic ebb in the cardiac circulation, during which blood leaves the heart, is produced by the forces of muscular contraction. The resistance opposed to this in the cardio-venous system is probably so small as to be of no material consequence, even to a weakly beating heart. It is the diastolic flow to the muscle-fibres that is dependent upon certain definite circulatory factors. Chief among these are the length of diastole, the intra-aortic diastolic pressure, and the lumen of the cardiac arteries. The intrathoracic negative pressure may act as a minor influence during inspiration.

The Length of Diastole.—The length of ventricular systole is fixed within variable limits, measuring it by the corresponding electrical complex, at about 0.43 of a second. It follows, therefore, that the length of diastole is in inverse ratio to the heart-rate. The slower the rate the more likely is the maximum supply of food and oxygen to reach every muscle-fibre during each cycle. Bradycardia, apart from the question of rest, should theoretically, therefore, be actively sought in the therapeutics of cardiac disease. Tachycardia on the contrary is likely to interfere, by diastolic shortening, with the blood-supply to the heart muscle. There is probably a critical rate above which starvation and anoxæmia of the muscle begins.

Apart from digitalis, the slowing action of which is mainly that of increasing heart-block in auricular fibrillation, there is no drug in clinical use actively capable of slowing heart-rate. Such an agency would be of great therapeutic value. In auricular fibrillation the irregular ventricular rapidity must result in a considerable variation in the cardiac blood-supply, for many of the auricular impulses reach the ventricle nearly empty of blood and thus incapable of raising the aortic valves and of producing a diastolic tension at all. The irregularity, apart from the inadequacy, of food-supply may be in some degree deleterious.

The diastolic flow of blood to the heart, apart from the length of diastole, is affected as regards its sufficiency by the amount of muscle to be supplied. Where great and progressive hypertrophy occurs, seeing that diastolic pressure remains fairly constant, there may come a point where even at a normal rate the blood-supply to the muscle becomes inadequate. Before this point is reached there will have been a gradual diminution in the heart-rate above which the diastolic flow is insufficient. More briefly, tachycardia becomes uneconomic to a greatly hypertrophied heart at progressively lower rates and in proportion to the degree of hypertrophy.

It is not without significance that pathological tachycardia as a rule accompanies a lowered systolic and diastolic blood pressure and that the largest hearts are to be found in aortic regurgitation where the diastolic pressure is also low. The tachycardia of a failing heart may be as much a factor in further failure as excessive hypertrophy may be in a heavily burdened organ. The coronary arteries as a rule enlarge to some extent with the enlarging heart, but not infrequently their lumen shares in the disease, syphilis or arterio-sclerosis, to which indirectly the enlargement is due.

The Intra-aortic Diastolic Pressure

By the diastolic pressure is here meant the whole of that period of intra-aortic tension that begins with the closure of the aortic valves. This intra-aortic diastolic tension is the chief factor determining the blood-supply to the heart muscle. The pressure must not only be of a certain degree, it requires to be exerted for a certain length of time to produce an adequate coronary flow. It is dependent upon five main factors: competence of the aortic valve, systolic output per beat, elasticity of the aortic wall, continuance of tone in the peripheral arteries, arterioles, and perhaps capillaries, and the systolic blood pressure. Inadequacy of any one of these five will influence either the height or the duration of the diastolic tension.

Incompetence of the aortic valve produces a lowering of the pressure at the beginning of diastole and a more rapid fall of pressure after it. Each of these changes becomes progressively more marked with the advance of the lesion, and each of them has a direct effect upon the diastolic flow of blood to the heart muscle-fibres. This is probably the chief reason for the fact that aortic regurgitation has a more serious prognostic significance than any other valvular lesion. Moreover, the various factors concerned interact to their mutual increase; the diastolic flow of blood is delivered at a lower pressure and for a shorter period to a larger mass of diseased muscle, very often through narrowed and rigid vessels.

The elasticity of the aortic wall is its main function in health. The organ is a conserver of power no less than of blood, and by its elastic recoil upon the contained mass it completes the systemic work begun by systole and accomplishes the transference to the heart muscle of oxygen and food. As the lesser vessels branch from the main trunk and become a network of finer and still finer twigs, the elastic tissue is replaced by muscle-fibres that sustain the hydraulic load at the desired pressure. There is thus no hard-and-fast line to be drawn between the two functions, elastic and muscular, in respect of their effect upon the diastolic blood-supply to the heart; inadequacy of either will provoke changes in both systolic and diastolic pressure. Nor is it possible in the human subject to prove the effects upon the coronary flow of the loss of elastic aortic recoil due to syphilitic aortitis, or of severe atheroma, or of the more diffuse forms of arterio-sclerosis. It is hardly likely that the effect in either case is entirely negligible. Arguing upon first principles it would seem that the aortic rigidity would impair and that the peripheral arterio-sclerosis, by raising the diastolic tension, might actually increase the cardiac circulation and, therefore, efficiency. Incidentally, the effect of a hot Nauheim bath is to slow the rate and to raise the peripheral blood pressure, both of which measures are to the advantage of the circulation through the heart muscle.

The systolic, and to a lesser extent the diastolic, blood pressure often falls with a pathological increase of the heart-rate, which in its turn frequently varies with the cardiac efficiency. Tachycardia is the first confession of a failing heart. To recover from failure and from the cellular poisons causing it, requires the oxygen, food, and rest which are to some extent denied by the increased rate, if this increase is above a certain point. The vicious circle set up can best be broken by a reduction in rate. The effect of coronary disease upon the cardiac blood-supply needs no elaboration. It should be remembered that the flow through the cardiac muscle does not begin until closure of the aortic valves when the pressure is lower than that of systole, that it continues with a falling pressure, and that therefore any diminution of the lumen will have a greater effect than in the case of a similarly diseased systemic artery.

Conclusions

The cardiac circulation is an inversion as regards rhythm of the systemic, as stated first by Thebesius in 1709. It is directly dependent upon the height and duration of the intra-aortic pressure during diastole. Any change in the latter is immediately reflected in the cardiac circulation. Aortic regurgitation starves the muscle of blood. The cardiac circulation may whether the case represented an acute myelogenous leukæmia with purpuric features or an essential thrombopenia with a marked stimulation myelocytosis

Following the operation in the present case there was temporarily a very notable improvement although towards the end the patient did show a small number of petechial spots and there was a certain amount of oozing from the gums, there was no more serious bleeding. The bleeding time was for a few weeks definitely shortened but later again became more prolonged Platelets did not appear to increase and in spite of the absence of hæmorrhage the red blood cells failed to increase.

The practical lesson seems to be that in typical cases of essential thrombopenia even in the presence of extreme anæmia one can recommend splenectomy with considerable confidence · in atypical cases the outlook is much more doubtful

A CASE OF
AMŒBIC DYSENTERY WITH LIVER ABSCESS
CONTRACTED IN ENGLAND

BY ALAN S SIMPSON, M R C S ENG.,
HOUSE SURGEON, KING S COLLEGE HOSPITAL.

IN THE LANCET of Jan 30th, 1926 a case of amœbic dysentery contracted in England was reported. The following case may therefore be of further interest, in that the patient who contracted amœbic dysentery with a subsequent liver abscess, has never been outside this country

H H aged 53 was admitted to King's College Hospital in December 1925, complaining of severe diarrhœa with much mucus and occasional traces of blood The onset was sudden three to four weeks before he came to hospital He said he had frequent calls to stool averaging eight or nine in the 24 hours

On admission the patient had a temperature of 103° F, pulse 96 he was very weak a tumour was palpable in the right lumbar region ill-defined tender and its relationship to the liver difficult to make out.

The blood count was red blood corpuscles 5 370 000 leucocytes 8300 · hæmoglobin 55 per cent. Differential count normal Wassermann reaction negative, urine normal

The stools were examined and the vegetative form of *Entamœba histolytica* was found in large numbers and some precystic forms

Laparotomy was performed and the tumour was found to be an abscess in the substance of the right hepatic lobe on the anterior aspect near the lower border It was about the size of an orange and contained yellowish pus which proved sterile on culture no amœbæ or cysts were found in this pus or in the subsequent discharges from the wound

Following the operation the patient was given a course of emetine bismuth iodide gr iii daily for 12 days, this did not cause any vomiting but slight diarrhœa occurred for the first three or four days

The patient was discharged from hospital in good health one month following his operation having put on weight.

I wish to thank Mr T Everidge for kindly permitting me to publish this case

---

MESSRS J B Lippincott Company announce the forthcoming appearance of a twenty-first edition of the United States Dispensatory and a seventh revised edition of Remington's Practice of Pharmacy The former is an authoritative encyclopædia of 2000 pages or more on pharmacy, chemistry botany and therapeutics and contains over 60 000 indexed subjects with tables and formulæ given both in apothecaries and metric scales. The latter is edited by Profs E F Cook and C H Wall of the Philadelphia College of Pharmacy and Science, with the aid of 63 collaborators and is intended to be a complete guide for the professional or commercial pharmacist.

BRITISH MEDICAL ASSOCIATION.
ANNUAL MEETING AT NOTTINGHAM

(*Continued from p 387.*)

SECTION OF PUBLIC HEALTH.
WEDNESDAY, JULY 21ST.

AT the first session of this Section, Dr P. BOOBBYER presiding, a discussion on

Poor-law Reform and Public Health

was introduced by Dr. T. MIDDLETON MARTIN (M O.H, Gloucestershire), who reviewed the history of the Poor-law and showed how the percentage of paupers had decreased from 5 3 in 1851 to 1 75 in 1921 and had then risen to an average of 3 7 for the four subsequent years He then indicated how social legislation had invaded the province of the Poor-law during the last 30 years The term "medical relief" first appeared in an Order of 1842 and indoor medical relief was administered on the deterrent principle up to 1867 when curative treatment became the dominant feature. In the report of the Royal Commission of 1905 the hope was expressed "that ultimately it may be possible to dispense altogether with the service of the district medical officer and that his duties will be shared among medical men practising in the district." Dr Martin submitted tabular statements showing the large number of health agencies which catered for a population of over 380.000 in Gloucestershire, and how the 8500 Poor-law persons in that population were dealt with Of the 212 practising doctors, 175 were insurance practitioners and 75 were Poor-law medical officers, and it would not therefore involve a very great change if the Poor-law patients were distributed like the insured persons among all practitioners willing to accept them, thus removing the stigma of the Poor-law so far as medical assistance was concerned A higher capitation payment would be reasonable but if the sum at present paid for these services to the Poor-law district medical officers were pooled a capitation rate double that of the Insurance Act would be available

Turning from domiciliary to in-patient treatment, Dr. Martin showed that of about 1900 hospital beds available for Gloucestershire s population about one-third were under the Poor-law. Of the latter accommodation about half was good and the remainder would require to be modernised. Additional maternity accommodation was required, especially in view of housing conditions In Gloucestershire a consultant and nursing service could readily be made available for the Poor-law patients and dental treatment in out-of-the-way districts could be obtained through peripatetic dentists

The services for the sick poor," as outlined by Dr Martin would include.

1 Domiciliary attendance by medical practitioners as far as possible on the lines of the present insurance medical practice, which tends towards a preventive health service.

2 In-patient treatment in hospitals (at present Poor-law infirmaries) and in additional accommodation (to replace unsatisfactory infirmaries) at existing or new cottage hospitals.

3 Consultant services—for example ophthalmic treatment.

4 Nursing assistance

5 Dental treatment as fully as practicable

6 Complete arrangements under the Scheme for the Extension of Medical Services whereby the sick poor may have immediate access to the particular form or place of treatment most appropriate to his case

The problem of the care of the necessitous section of the population has Dr Martin concluded been one of gradual evolution the next stage would naturally be to provide care and treatment of the sick amongst them on the lines recently developed for another large section of the community, thus avoiding unfortunate class distinction

Dr JAMES FENTON (M O H Kensington) discussed the problem in London and showed how efficiency and progress were retarded by the division of health duties amongst five executive authorities—viz, county council, borough council Poor-law authority, and the fine supporting stroma becomes correspondingly prominent These centres, although prominent, are never active and show no mitosis Relative to these centres the lymphoid tissue is deficient There is much blood in the splenic sinuses The lining endothelial cells are not prominent The splenic pulp is less cellular than normal and contains fewer lymphocytes Eosinophils are relatively frequent There is no demonstrable deposit of iron

We are indebted to Dr. Kark, under whose care the child was in the earlier stages of her illness, for the notes of her condition at that time

She was seen by one of us (A R McL) in February, 1926 There had been no further bleeding, and she was said and appeared to be in perfect health Unfortunately the parent would not allow any blood examination

CASE 2 —Mrs M , aged 28 Admitted on July 9th, 1925, to the New Somerset Hospital on account of uncontrollable epistaxis without local cause

Previous history Patient stated that she had been healthy, but admitted on questioning that for years she had bruised readily Menstruation had been normal Tonsils removed 15 years ago on account of repeated sore-throats, but without making much difference to the frequency of the attacks Diphtheria 18 months before admission One child, aged 4, born without difficulty Says she had a three months miscarriage in October, 1924, without excessive loss

Family history No members of the family had suffered from bleeding

History of present illness In November, 1924, patient began to suffer from repeated epistaxis Shortly after this she noticed the presence of small purpuric spots all over the body and limbs, and the appearance of large bruises without any known cause The teeth also bled easily She became extremely pale, breathless, and easily tired In February, 1925, she became pregnant The bleedings, particularly the epistaxis, continued until admission, and she became more and more anæmic

On admission patient was fat and flabby, mucous membranes extremely pale There were a moderate number of petechiæ and ecchymoses over the body and limbs There was frequent oozing from the gums and repeated epistaxis occurred, which was not efficiently controlled by packing Otherwise no bleeding from the mucous membranes The spleen was not palpable The uterus extended almost to the umbilicus The fundi oculi showed œdema and blurring of the discs and several hæmorrhages in each The circulatory system showed a moderate sinus tachycardia, and a systolic murmur at all the orifices The urine at times showed a trace of albumin, but functional renal tests were normal

Blood On admission Hb 22 per cent , red cells, 800,000 , white, 5000 , polymorphonuclear, 30 per cent , lymphocytes, 68 per cent , transitional, 1 per cent , hyaline, 1 per cent There was considerable anisocytosis with the presence of numerous megalocytes Blood platelets were extraordinarily scanty, and in a differential count none might be seen at all When seen they were isolated and generally large Bleeding time was much prolonged—from 11 to 15 minutes—coagulation time rather diminished Blood-clot after 12 hours almost completely non-retractile Van der Bergh test negative

After admission she continued to have repeated epistaxis, oozing from the gums, and small hæmorrhages into the skin The blood remained much the same The differential leucocyte count varied slightly but there was always a distinct relative lymphocytosis

On August 10th, 1925, Dr McLachlan removed the spleen preceded by a blood transfusion The operation was difficult, as the moment the anæsthetic was started profuse epistaxis occurred which could not be adequately controlled The stomach was dilated, the uterus extended to the umbilicus, and the spleen could not be delivered and had to be tied in the depths The patient was removed from the table in a very bad condition Following the operation, however, the patient had an astonishingly easy convalescence All bleeding stopped, and apart from a very slight epistaxis ten days after the operation, the patient had no further serious hæmorrhage

Two days after the operation the blood showed the presence of numerous nucleated red cells, but there was no apparent increase in platelets The bleeding time was reduced to about four minutes Ten days after the operation a second blood transfusion was given This was also followed by the transient appearance of nucleated red cells in the blood For six weeks the patient continued to improve, there was no further bleeding, the pregnancy was uninterrupted and the patient felt so well that she was very anxious to get up

In spite of the absence of bleeding and the clinical improvement the blood did not show corresponding improvement, and the red cells never rose above 1 000,000 There was a slight evening rise of temperature From the middle of September there was again slight oozing from the gums and a few petechiæ appeared on the skin There was, however, no serious hæmorrhage On Oct 1st the red cells were 765,000 and the white cells 6500, with a sudden increase in the relative lymphocytosis to 76 per cent. General condition certainly not so good On Oct 5th spontaneous labour set in and the patient was easily delivered of a still-born child with very little loss of blood. Four hours after delivery, however, she suddenly died of cardiac syncope No autopsy was permitted

Spleen Prof Ryrie reported "There is no change in the connective tissue trabeculæ The smaller arterioles show hyaline degeneration The larger vessels are not altered The Malpighian bodies are smaller than normal and ill-defined at their edges Although the germ centres of lymphoid tissue are prominent this is not due to excessively active lymphoid tissue, but to an increased content of large cells of the supporting stroma There are remarkably few red blood cells in the pulp Polymorphs, large mononuclear cells, and plasma cells are present along with rather more eosinophil leucocytes than usually seen The endothelial cells of the sinuses are prominent largely due to a deficiency of other cells There is no excess of iron pigment and no evidence of excessive phagocytosis "

Discussion

Case 1 is a typical example of essential thrombopenia The bleeding at once ceased after splenectomy, and the patient has remained free from symptoms for over two years

Case 2 is more difficult It is generally admitted that border-line cases between aplastic anæmia, purpura hæmorrhagica, and acute myelogenous leukæmia occur, in which at present at any rate it may be impossible to make a differential diagnosis Also some hold that an essential thrombopenia may terminate in a secondary aplastic anæmia In view of the severe anæmias which may develop in pregnancy, it is possible that the pregnancy may have influenced the blood condition An aplastic type of anæmia is rare in pregnancy though it has been described by Larrabee [2]

Purpuric eruptions in pregnancy are rare but have not infrequently been described Rushmore [3] collected 47 cases but they are not all of the same nature and of very different severity Out of 44 cases there were 26 maternal deaths

The occurrence of pregnancy during a remission in chronic purpura hæmorrhagica has been described several times, and labour has occurred without undue bleeding Kaznelson's first case of splenectomy for purpura hæmorrhagica was a woman who had been purpuric since early youth Four years before operation, in a remission, she had given birth to a child without difficulty Nagy [4] reports a similar case without splenectomy In both these cases, however, the pregnancy occurred during a remission of the purpuric symptoms With regard to the present case there is no doubt that the purpuric symptoms appeared several months before the onset of the pregnancy The absence of any symptoms of the anæmia before the onset of the hæmorrhages, the notable diminution of the platelets, the prolonged bleeding time, the normal coagulation time, the non-retractile clot are in favour of a diagnosis of primary essential thrombopenia Against the diagnosis of a primary essential thrombopenia are the relative lymphocytosis and the somewhat raised colour index

Lucas and Fleischner [5] report a case of splenectomy in a child of 3½ with purpuric symptoms in which the blood showed a high colour index, a relative lymphocytosis with in addition a considerable number of myelocytes Splenectomy was not followed by any improvement and at a partial autopsy almost complete aplasia of the bone-marrow was found so that the authors were unable to say that the condition was a true aplastic anæmia or a terminal aplasia in the course of a leukæmia Farley [6] reports a case of a girl aged 18 with all the findings of an essential thrombopenia except that myelocytes were unusually prominent Splenectomy was performed with distinct temporary improvement which persisted only a few weeks After autopsy Farley was unable to decide evidence The proportion of protein, fat, and carbohydrate in an adult s diet could be varied considerably without producing signs of ill-health, and the same was being increasingly recognised in the case of infants, providing the diet was adequate in certain other qualitative respects The amount of vitamins necessary to maintain good health in animals varied with the circumstances Thus Mellanby had shown that the vitamin A must be increased if the cereals were increased, and Plimmer had shown that vitamin B must be increased if the total energy value of the diet was raised Again, rickets could be produced in dogs receiving butter and oatmeal and prevented by the addition of extra calcium , and ultra-violet rays may compensate for the absence of vitamin D On the basis of this work, rickets might develop in children under several sets of conditions First, from deficiency of the antirachitic vitamin, in an otherwise well-balanced diet—e g , a breast-fed infant of a mother whose stores of vitamin are low Secondly, from deficiency of calcium in a diet low in antirachitic vitamin—e g , a child receiving little milk Thirdly, from excess of cereal, especially oatmeal, unless the excess of cereal is balanced by an increase of vitamin D Fourthly, from absence of solar irradiation combined with relative deficiency of vitamin D—e g , children brought up in smoky industrial areas

Dr Cowell went on to discuss the relative advantages of artificial sunlight clinics and cod-liver oil Irradiation only compensated for the lack of vitamin D, although it might temporarily mobilise existing stores of vitamin A in the body Although irradiation alone might cure rickets, cod-liver oil by supplying both vitamins A and D was the more effective method Irradiation impressed the mothers as a spectacular proceeding Cod-liver oil was an old-fashioned remedy, often given irregularly, and might be disliked by the children if not in the form of a palatable emulsion Some very few cases of renal rickets did not yield either to irradiation or cod-liver oil, and some cases responded only to subcutaneous injections of concentrated preparations of the oil These rare cases did not affect the main conclusions

Turning from rickets to malnutrition or marasmus in infants, Dr Cowell described the remarkable results which were being obtained in the Royal Infirmary, Sheffield, by the provision of a vitamin-rich diet for such infants—results which justified the contention that many cases of marasmus were due to vitamin deficiency No humanising or modification of the milk was practised beyond simple dilution when necessary , but the diet was enriched by the addition of cod-liver oil emulsion marmite, and orange juice, in order to make sure of adequate supplies of vitamins A, B, C, and D respectively The vast majority of these babies improved quite rapidly Good results were being claimed for the artificial light treatment of infants at some infant welfare centres He had occasionally met with marasmic cases in a stationary condition which responded to ultra-violet irradiation, and one or two where the irradiation of the milk started the improvement He could not explain these rare cases, but they did not affect the main argument that most of such infants responded to the vitamin-rich diet alone

Dr Cowell went on to show the prolonged effect on the young of good feeding of the pregnant and lactating mother The diet of the hen affected the vitamin content of the egg and the diets of cows and women had a similar effect on the milk In bottle-fed infants and all young children the prevention of rickets could be ensured by giving cod-liver oil Even infants in the first few weeks of life tolerated the oil in almost all cases The dosage should be ½ drachm in the day at birth gradually increased to 2 drachms and not exceeding that amount at age 2–3 years After weaning, the child s diet should include milk (the only considerable source of calcium in common foodstuffs) and other vitamin-rich foods Such simple dietetic measures would not only prevent rickets and diminish the amount of marasmus and malnutrition They would, as Mrs Mellanby had shown, produce teeth which were better formed and less liable to decay Lastly, there was much evidence that the resistance of the body would, by these means, be raised against both respiratory and alimentary infections Rickety children were peculiarly liable to catarrhs, bronchitis, and pneumonia Puppies getting cod-liver oil never had pneumonia The routine administration of cod-liver oil had apparently largely reduced the incidence of diarrhœa in institutions, such as homes for illegitimate babies

It would appear possible, Dr Cowell concluded, at the present moment practically to eliminate rickets, to improve enormously the condition of the teeth of our people, to lessen the infant mortality from malnutrition, diarrhœa, and respiratory infections, and in general to raise the standard of physique and health

Dr **Helen M M Mackay** (London) spoke from the clinician's point of view The chief known specific food deficiencies in this country were deficiencies of iron, the organic antirachitic factor, the antiscorbutic vitamin, and of iodine in certain districts There might be others but their presence among the population was as yet unproven For example, there was not sufficient reason for assuming that constipation and digestive disorders were frequently due to the deficiency of vitamin B Dr Mackay went on to point out the wide distribution of vitamin B and to say that if there were a widespread deficiency she would expect occasional cases of beri-beri to occur Similarly, keratomalacia and pellagra were extremely rare The infant, until it received a mixed diet, was largely dependent for iron on the store in the liver at birth This store was laid down in the later months of pregnancy, so that the premature infant was specially liable to anæmia The iron content of both human and cow's milk was low Minor degrees of anæmia were quite common among full-term infants The prophylaxis of this infantile anæmia required more study The deficiency of the antirachitic factor very commonly showed among children, but it was not established that widespread ill health among adults arose from the cause It was found that 15 per cent of unselected new out-patients, aged 4 to 13 months, at the Queen's Hospital for Children had X ray evidence of rickets during April, and in the northern industrial towns the incidence was much higher Cod-liver oil was the best source of this factor and it was a pity that the public, under medical direction, wasted large sums on proprietary preparations which were relatively poor sources of this vitamin A cod-liver oil emulsion, begun gradually and given three times a day in the bottle (say, 1 drachm of the oil daily) was well tolerated by almost all infants Tetany (a common cause of convulsions between 6 and 24 months of age) and respiratory infections were also caused by the deficiency of this factor They had observed a much smaller incidence of respiratory infections (including otorrhœa) among the infants at the Vienna clinic who were having cod-liver oil If all bottle-fed and all breast-fed infants who were little out of doors had cod-liver oil during the winter rickets would be practically abolished infant respiratory troubles and convulsions would be lessened, and the amount of dental caries would be decreased Scurvy was not common now in London The contrast with Vienna was very striking and she attributed this to the widespread use of orange juice in London Tomato juice needed popularising as a substitute when oranges were dear (instead of the very much less effective grape juice) Another common deficiency was water The benefits of a liberal supply of water were very striking in diarrhœa and high pyrexia for instance, with pneumonia The public were afraid of water in such conditions and needed instruction

Sir **Percy Bassett-Smith** (London) spoke from the tropical point of view He discussed the various forms of beri beri and stated that in tropical climates deficiency diseases mostly centred round the

Metropolitan Asylums Board, and the Insurance Committee The underlying principle of the London Public Health Act of 1891 was executive borough councils and an almost exclusively supervisory county council, but that principle was departed from when the county council was made the educational executive authority in 1907. After referring to the provisional proposals of the Minister of Health for Poor-law reform, Dr Fenton said the principle of having the individual under the supervision of one single authority throughout the course of his life would be generally accepted, but London was too big for a single authority to be charged with all executive health functions The Poor-law institutions had 46,800 beds and the M A B. institutions 23,000, while the total beds in the London voluntary hospitals only numbered 13,000 If the L C C. had to control the two first-named groups of institutions it would be necessary and desirable to charge the borough councils with the duty of carrying out all local health services of a non-residential character Each borough would thus have transferred to it the school medical service, supervision of midwives, inspection of common lodging-houses, and also the work of the Poor-law guardians (other than that in connexion with residential institutions), and of the Insurance Committee The county council, in addition to being the institution authority, would remain the supervisory and coordinating authority and would become a provincial board of health for London, thus relieving the Minister of Health of much detailed work Thus two authorities working in close cooperation would operate in each area instead of five as at present It is only, Dr. Fenton concluded, by such distribution of functions as that outlined that metropolitan public health administration can become efficient, elastic, and capable of fullest development In this way only can administration be really democratic, enabling the citizens of each borough to have easy access to local representatives and responsible officers in their own areas, for central executive administration over an area so vast as the metropolis must, of necessity, be bureaucratic.

Dr R P GARROW (M O H, Chesterfield), speaking from the point of view of non-county boroughs and urban districts, voiced the strong objection of such districts to being placed under the control of the county councils They also resented the raising of the population limit for county boroughs from 50,000 to 75,000 The control by the county councils would not promote unification and prevent overlapping, but have the opposite effect. Public health was becoming more personal and the local touch must be maintained The alternative was a radical revision of the areas and to make the local authorities of the enlarged areas responsible for all health services in their districts The new areas should have a considerable town as their centre, to which they would look for their main hospital provision and which they would regard as the focus of health administration

Dr ARTHUR L BALY (chief M O, Lambeth Board of Guardians) thought there would be a waste of public funds unless the present Poor-law system were retained and controlled in areas of reasonable size by local authorities He quoted with approval the scheme outlined in the annual report (1924–25) of the New York United Hospital Fund to give the patient "a single source on which he can depend for his health" Such a scheme in London would necessitate the division of London into areas of reasonable size with a single authority for each in control of domiciliary treatment and all institutions, including fever, mental, and all specialised branches of medicine This ideal could be attained most readily by modification of the existing Poor-laws, so as to ensure that they were properly administered The Poor-laws sanctioned the provision of every possible form of medical relief, and the work done depended upon the character of the guardians and their officers If efficient boards of guardians were established, it would be possible to attain the ideal of one authority for each area to the infinite advantage of all concerned, including the ratepayer. They ought avoid, on the one hand, the evils associated a large central medical authority and, on the oth the transference of the guardians' duties to authorities which had not in any way demonstrat their superiority to the existing guardians If it w intended to centralise all the work in London on th county council, a satisfactory solution might b obtained by transferring the supervisory powers the Ministry of Health to the county council, London into areas of convenient size, and p each area under the control of a local committ empowered to carry out its work in its own way A further point made by Dr Baly was the undesirabl tendency to amalgamate medical insurance and assistance Insurance should be on an basis and public assistance not fully paid for entail local disfranchisement

Dr T EUSTACE HILL (M O H, co Durham thought the B M A memorandum had overlook the need for unification and the fact that coun councils had had considerable experience in sanita administration He did not think it would be difficult for the county council to divide Durham into about 13 districts and do the work through a whole-time M O H for each district

Dr D KIRKHOPE (M O H, Tottenham U D) said his district had a population of about 150,000 and referred to the varying sizes of the counties as likely to work against efficiency The Poor-law stigma might be removed by a change of name—e g, the Edmonton Union Infirmary was now the North Middlesex Hospital They must preserve local interest in the administration

Dr STELLA CHURCHILL (L C C) emphasised the enormous overlapping, and doubted the wisdom of transferring the administration of hospitals with 70,000 beds to the county council It would retain local contact if they were under the borough councils

Dr JAMES WHEATLEY (M O H, Shropshire) said unification was absolutely necessary London was quite a separate and special problem

Dr H SCURFIELD instanced the progress made in Hampshire and Essex towards unification by slightly different methods

Prof F E WYNNE (M O H, Sheffield) referred to the harmonious cooperation of council and guardians and described how the two boards in Sheffield had been amalgamated, and the institutions of one of the boards had been taken over for the purposes of the council No one wished to abolish efficient authorities, but many rural district councils were not efficient

Dr H B BRACKENBURY (London) said the differences of opinion were more apparent than real The memorandum of the B M A. had been approved in principle by the representative body since 1918 The Bill would be introduced next session but would not be dealt with till the session after Rural areas required different treatment to populous urban areas The Bill gave county councils power to deal as they liked with the transferred duties They might delegate to the local authority The county council's power of supervision was new He thought large urban districts should be exempted from county supervision, but did not object to the county council's power to act in default

Dr MARTIN, in replying, said the transfer of powers was not really on account of the incompetence of the guardians but because of the great need for unification of the medical services He thought the county councils were the most suitable bodies to administer the transferred powers

THURSDAY, JULY 22ND

Food Deficiency and Preventable Illness

Dr STUART J COWELL (Sheffield), in opening the discussion on this subject at the second session, said it was probable that a great deal more illness was due to defective diets than was at present recognised, but he proposed to confine himself to the discussion of common diseases as to which there was positive

(3) *Diamond-shaped hæmorrhages with pale centres*—Seen more frequently in the anæmias and leukæmias

(4) *Large mottled hæmorrhages*—Usually near the disc, or along the temporal vessels; probably due to a leak from a larger vessel than a capillary, but the source cannot usually be identified

(5) *Pre-retinal or subhyaloid hæmorrhages*—Most frequent in the macular region, may occur in vascular disease, frequently in leukæmia

(6) *The hæmorrhages of infective endocarditis*—Due almost certainly to lodgment of minute infected emboli, and so must be on the heart side of the capillaries Few cases of the disease occur, said Mr Moore, in which retinal hæmorrhages are not present It is more common in this disease than in any other to see the blood extending along the vessels as though it were effused into the perivascular sheath

(7) *Hæmorrhages associated with subarachnoid hæmorrhages*—In fractures, or cerebral hæmorrhages, and in ruptures of aneurysms of the circle of Willis, probably caused by obstruction to the venous flow

(8) "*Cotton-wool patches*"—White patches, probably the result of hæmorrhages, seen in some cases of anæmia, and usually associated with hæmorrhages of other types, may closely simulate early renal retinitis

Absence of hæmorrhages in cases of chlorosis, formerly a common disease, was, Mr Moore said, very interesting when contrasted with their almost invariable presence at some time in the course of fatal cases of leukæmia and pernicious anæmia In arterio-sclerosis retinal hæmorrhages are not directly due to the increased arterial pressure; the pressure in the capillaries is lower than normal probably, and the hæmorrhages may be an expression of the consequent impaired nutrition of the endothelium Hæmorrhages due to obstructed venous outflow may be classified into —

(A) *Cases of general venous engorgement*—(1) General constitutional conditions, such as whooping-cough or vomiting, (2) the hæmorrhages produced apparently by the process of birth, (3) severe compression of the chest.

(B) *Due to a local cause outside the eyeball*—(1) Subarachnoid hæmorrhage, (2) papillœdema, (3) some cases of thrombosis of the cavernous sinus

(C) *Due to a cause within the eyeball*—(1) Obstruction of the central retinal vein or one of its tributaries

In all these groups apparently the back pressure due to the obstruction is the cause of the leakage

It would seem then, Mr Moore concluded, that leakage of blood occurs. (1) from arterioles, from lodgment of infected emboli (as in infective endocarditis), (2) from the capillaries, either from poisoning of the endothelium, as in renal disease, or from impairment of its nutrition, as in the anæmias, (3) from the venules, from mechanical causes, as in a hindered venous outlet from the eye As regards the changes which take place in retinal hæmorrhages, it may be said that all hæmorrhages simply fade away, gradually becoming smaller, and undergoing no other change in colour. The length of time required for their complete disappearance varies enormously Mr Juler has found retinal hæmorrhages in 15 5 per cent of new-born infants, apparently produced by the process of birth These hæmorrhages may disappear in so short a time as four days Large dense hæmorrhages, on the other hand, may take many months for their complete absorption. Hæmorrhages, no matter how large, produce no permanent change in the retina unless the external limiting membrane is lacerated

Dr C O HAWTHORNE (London) pointed out that "undue fragility" of the retinal blood-vessels might possibly account for some cases (e g, Eales's disease): some such condition seemed to be present in hæmophilia, and in those cases where bruising followed on very trivial traumatism such as a friendly grasp on the arm Accepting (1) that retinal hæmorrhages occur without any prejudice to sight, and therefore without the knowledge of the patient; (2) and that they may be the first, and for a comparatively long time the only evidence of serious disease—it seemed logical to argue that no safe diagnostic position can be reached without an ophthalmoscopic examination; and, further that such an examination if negative at first should be made repeatedly as is done usually in observations of pulse or temperature for diagnostic purposes.

Mr. G. H POOLEY (Sheffield) dealt especially with the prognosis of life in cases where retinal hæmorrhages are found. The association of retinal œdema added to the gravity of the prognosis In renal cases the younger the patient the more serious the prognosis as a rule A man of 65, for instance, might live ten years or more after extensive retinal hæmorrhages had occurred Cases with striate hæmorrhages only often lived much longer than was formerly taught

Mr. M L HINE (London) gave a warning against too gloomy a prognosis In one case of extensive hæmorrhage at the end of six months vision was still very poor, but three months later it was 6/6.

Mr. T. HARRISON BUTLER (Coventry) quoted a case of the opposite kind; in a girl referred to him on account of headaches he found one small but definite flame-shaped hæmorrhage She was examined by a physician who found no disease; but she died a fortnight later of uræmia

Mr N BISHOP HARMAN (London) referred to a case of a man of 72 with very numerous flame-shaped hæmorrhages who was known to have had them for at least ten years

Mr A. CHRISTIE REID (Nottingham) said that it was clear that our ideas on the subject of retinal hæmorrhages needed to be revised; a new classification appeared to be imminent

Dr A VERREY (Lausanne), Mr. E J PRIMROSE (Glasgow), Dr P MACDONALD (York), Dr. DAVID WILSON (Torquay), Dr. N. L. G. LEASK (Glasgow), and Dr. HARRIES JONES (Northampton) also took part.

Demonstrations

Mr. T HARRISON BUTLER (Coventry) read a paper on Slit Lamp results by Simplified Methods

Mr. N BISHOP HARMAN (London) described with lantern slides the work at Chorley Wood College (Herts) for girls with little or no sight.

In the afternoon Mr BASIL GRAVES (Liverpool) operated on two cases, demonstrating Wheeler's (New York) method of capsulotomy and iridotomy. Mr POOLEY demonstrated his operation for lacrymal cases A short incision is made over the sac, going right down to the bone; a gouge is introduced and driven through the bone into the nasal cavity by four taps of the hammer so as to procure a free opening; after using a sharp spoon a bunch of ten-day catgut is placed in the opening made and the incision is sutured The whole operation is completed in a few minutes It has been done with good result in a number of cases

Dr G YOUNG introduced a brief discussion on the causation of the steamy appearance of the cornea in cases where the surface is perfectly smooth In a recently enucleated eye the same appearance can be produced at once merely by lateral compression with the fingers; the steaminess disappears immediately when the pressure is removed He suggested that the appearance might be caused by polarisation of light due to the layers of the cornea becoming shifted against each other. The point could, he thought, be elucidated by slit-lamp observations Mr BUTLER and Mr. GRAVES regarded the observation as of extreme interest.

Nagel's Anomaloscope.

Dr ARNOLD VERREY (Lausanne) gave a demonstration of Nagel's anomaloscope for defects of colour vision This is a simple apparatus for matching spectral colours It includes a small spectroscope furnished with a dispersing prism The tube of the collimator turned toward the source of light carries the slit apparatus, composed of one double slit and one single slit. The field of vision is separated into two parts by a horizontal line The upper part is filled (depending on the setting of the slit) either with the spectral green of the thallium line (530 μμ) or with the spectral red of the lithium line (670 μμ), or lastly with a mixture of the two, while the lower inadequate supply of vitamin B, which could be obtained in a concentrated form from rice polishings as "ticque-ticque," or from yeast as marmite The diet which produced beri-beri in the few could hardly fail to have a deep-seated and bad physiological effect on the many People might appear well for a long period on a diet deficient in vitamins, but they would inevitably develop some form of constitutional disease, slowly evolved

Dr **James Wheatley**, speaking from the public health standpoint, showed that wholemeal bread contained seven times as much vitamin B as white bread, when both were made with yeast Education of elected bodies in these food matters was very important as a first step and might lead up to the taxation of undesirable forms of food, such as white flour and refined sugar, facilities for the production of the better foods, and the addition of substances to certain staple articles of universal consumption—e g , iodised table salt Unfortunately, the fat-soluble vitamins were found in the most expensive foods There should be a great extension of the scheme for supplying milk to expectant and nursing mothers and young children. The supply of milk for the rural population should be safeguarded Dairy farmers should supply such milk at a price between the wholesale price and the retail town price. The keeping of goats should be encouraged and facilities for allotments increased Grass feeding of dairy cattle should be encouraged Fat-soluble vitamins might be added to margarine. The proof that food deficiencies were causing enormous damage to health was, to his mind, conclusive The foods mentioned by Dr. Mackay as sources of vitamin B were foods which a great part of our population went short of We must have better food and could not rest content with the ideal of a nation brought up on cod-liver oil, valuable though it was

Dr **Leonard Hill** (London) referred to the activation of cholesterol to form vitamin D. The operation had to be done with great care. He thought cod-liver oil had been well tried and that light treatment would do what cod-liver oil could not.

Dr D. G **Greenfield** (Rushden) spoke as to the great scarcity of milk in rural districts He thought the right kind of food more important than light, and suggested that focal infections and pyorrhœa might be caused by food deficiencies More research was needed

Dr **Scurfield** confirmed from his experience Dr Wheatley's view, in contrast to Dr Mackay's, that there was a real danger of a vitamin-B shortage As regards bread and flour, he thought the first step should be legislation to secure that the purchaser should know what he was buying He would like to see jams and marmalade tested for their vitamin content He imagined the cooking of the fruit would not kill any vitamin B which it contained He also referred to the very conflicting results reported from the light treatment of tuberculosis

Dr B **Spearman** (Zanzibar) said it was a mistake to think primitive savages did not suffer from deficiency diseases Many natives were liable to catarrh and pneumonia and had little resistance to disease There was no rickets on the mainland, but there was in Zanzibar among the Indian women who lived a purdah life Some of the native tribes had very monotonous diets

Dr. E V **Ashcroft** (Manchester) said the rickets in Ancoats came from the dirty houses with slatternly mothers and a teaspoonful of cod-liver oil per day did wonders

Prof **Wynne** did not in the least agree with Dr Hill that cod-liver oil had been well tried After it had been supplied for a patient, it was often taken very irregularly or not at all

Dr. **Cowell**, in replying, said the advocates of better food and the use of cod-liver oil did not neglect light treatment.

SECTION OF OPHTHALMOLOGY

This Section met on two days On the first a joint meeting with the Section of Neurology and Psychological Medicine discussed migraine The report of this discussion appeared in our issue of August 21st, p 384

Thursday, July 22nd

An Operation for Glaucoma

On the second day the Section met at 9 30 A M at the Nottingham Eye Infirmary, where Dr **George Young** (Colchester) demonstrated his operation for glaucoma After reflecting a conjunctival flap (usually below) he makes two separate trephine openings through the sclera at the limbus a few millimetres apart with a 1 mm Elliott trephine These openings are cleared by the removal of such portions of the ciliary body and muscle as prolapse, or as is required to procure a clear opening, allowing aqueous fluid to ooze for a few minutes Massage of the eye is begun immediately after the operation The essential points are the formation of *two* separate small trephine openings *behind* the attachment of the iris to the corneo-scleral junction The anterior chamber is not opened The operation has in his hands given satisfactory results

Significance of Retinal Hæmorrhages

A discussion on this subject was opened by Mr R **Foster Moore** (London), whose paper was read in his absence by Mr A **Christie Reid** (Nottingham) Recent investigations by Dale and Laidlaw, Dale and Richards, and Krogh had, he said, added new interest to the subject, and he put forward the following classification as reasonable (excluding such retinal hæmorrhages as arise from disease localised in the eye) —

(A) *Disorders of metabolism* —(1) Renal disease, (2) diabetes, (3) scurvy

(B) *Diseases of the hæmatopoietic system* —(1) Arterio-sclerosis, (2) severe anæmias (or severe cachexias), (3) leukæmias, (4) infective endocarditis, (5) Vaquez's disease, (6) hæmophilia

(C) *Obstructions to the venous flow* —(1) Thrombosis of the retinal veins, (2) thrombosis of the cavernous sinus, (3) subarachnoid hæmorrhage, (4) papillœdema, (5) during birth, (6) severe compression of the chest

Krogh had shown, said Mr Moore, that the capillaries have outside their endothelial lining a loose meshwork of actively contractile cells (Rouget cells) which are under nervous control By means of these cells the capillaries are capable of extreme contraction or dilatation The transition between arterioles with a complete muscular coat and capillaries is sharp and abrupt On the other hand, the transition between venules and capillaries is more gradual, for the venules have at first, like the capillaries, an outer coat formed of a wide-meshed network of Rouget cells, through the meshes of which free interchange between the blood and tissue fluids can occur as in the capillaries No passage of cells from the blood into the tissue spaces occurs in conditions of health Experiments seem to show that what makes such passage of cells possible from the interior of the capillaries is a poisoning or impaired nutrition of their endothelial cells Certain poisons seem specially to affect the capillary walls, so that they no longer maintain an inviolate barrier against the passage of cells from their lumen In diabetes, or nephritis, such toxins are probably the cause of the hæmorrhages In leukæmias, pernicious anæmia, and cachexias, defective nature of the blood may perhaps act in the same way on the endothelial cells

Passing on to the different types of retinal hæmorrhages Mr Moore enumerated eight types

(1) *Flame-shaped hæmorrhages* —These are the commonest ; they may be very small, seldom very large, are situated in the nerve fibre layer, and are a common type in renal retinitis and arterio sclerosis

(2) *Rosette or blotch hæmorrhages* —Small, situated in the deeper layers, found especially in diabetes, multiple, more or less circular, with an irregularly crenate edge

occupy nearly two-fifths of the whole The articles are readable and interesting, and represent an adequately conservative outlook They are worth the attention of English readers because they reflect the small differences in point of view and practice which one nation does well to learn from another, and so improve the pool of knowledge common to all

UTERINE HÆMORRHAGE

By SAMUEL J. CAMERON, M B Glasg, F R F P and S Glasg Lecturer in Clinical Obstetrics, University of Glasgow, and JOHN HEWITT, M B Glasg, Assistant Obstetric Surgeon to the Glasgow Royal Maternity and Women's Hospital London Edward Arnold and Co 1926 Pp 208 8*s* 6*d*

THIS little volume, written primarily for the general practitioner, deals with the most important single symptom met with either in obstetrics or gynæcology The authors do not claim that it is an exhaustive treatise on uterine hæmorrhage, but rather an endeavour to discuss the subject in a practical way, and thus to help those called upon to treat cases In this aim they have been largely successful The book is arranged in two parts, with an appendix on the treatment of hæmorrhage and shock, which contains a simple account of the technique employed in blood transfusion and the methods used in grouping donors Part I. deals with obstetrical hæmorrhage, including extra-uterine pregnancy. A considerable amount of the subject matter of this section has already appeared in a Glasgow Manual of Obstetrics, which was edited by the senior author, and reviewed in our columns last year Part II treats of gynæcological hæmorrhage both physiological and pathological The relationship of the ductless glands to the menstrual function is discussed, and the experimental work of Blair Bell and Beckwith Whitehouse on menstrual fluid is referred to In the section dealing with carcinoma of the cervix treatment by radium is discussed, and although the authors have treated many cases by this means they think it is wise to maintain for the present a healthy scepticism regarding the ability of radium to cure cancer They restrict its use to inoperable cases where a certain measure of relief may be expected The authors do not advocate radiotherapy in the treatment of fibromyomata, but prefer either myomectomy or hysterectomy if the patient is fit enough to stand these operations For menopausal hæmorrhage, on the other hand, they have, like other observers, found radiotherapy satisfactory, operation being rarely required

The book on the whole is well written, sound, and bears the imprint of a large practical experience of the authors It includes little that can be described as new or original but it contains an excellent résumé of current views and should appeal to the student and general practitioner alike

DIATHERMY

Die Diathermie Fifth edition By Dr KOWARSCHIK, Primararzt des Institutes fur Physikalische Therapie im Kaiser-Jubilaums-Spital der Stadt Wien Vienna and Berlin. Julius Springer 1926 Pp 239 M 15

THE publication of a fifth edition of this work 15 months after the fourth shows the popularity of Dr Kowarschik's "Diathermie" Not much has been added to the present edition A new diathermy machine, by Schulmeister, of Vienna, is described This is fitted with the "open" spark-gap, the type which is most generally used in Germany and Austria An interesting experiment by Ludin is included A temperature-recording device was introduced into the human stomach and electrodes were placed on opposite aspects of the trunk so as to include the organ in the path of the diathermy current The temperature was observed gradually [illegible] and the rise increased as the current was strengthened It is doubtful, however, whether this rise was local and confined to the path of the current The duration of the passage of the current was three and a half hours During this time there must have been convection of heat to other parts of the body by the blood stream and an elevation of the general as well as the local temperature A description is given of some other experiments, also by Ludin, which show the action of diathermy on the intestines in increasing peristaltic movement These experiments are illustrated by graphic records.

The author shows a praiseworthy restraint when he advocates diathermy in therapeutics, and those who read his book will learn the maladies in which the treatment will produce good results in the majority of cases as well as those in which some benefit is only occasionally obtained

TEXT-BOOK OF EXPERIMENTAL PSYCHOLOGY.

Third edition By CHARLES S MYERS, M A., M D, Sc D., F.R S, and F. C BARTLETT, M.A Cambridge The University Press 1925 Pp 121. 7*s*

ADMIRABLE as were the first and second editions of this laboratory handbook this new edition marks a considerable advance both in arrangement and content While the basic exercises dealing with the senses, reaction-time experiments, psycho-physical methods and statistics remain the same, there are considerable additions in the treatment of the higher mental functions and perception. Free association, made familiar to us through the technique of psycho-analysis, is treated scientifically The method here adopted is that of Jung's list of association words rather than the continued association of the Freudian technique A student might be well advised to try the continued method in order to realise for himself the affective elements involved and thus discover in himself the process of constellation formation. A further useful addition is Experiment 3 on the perception and reproduction of forms of growing complexity Such experiments have considerable theoretical interest in the light of the *Gestalt theory*. The section on auditory testing receives much fuller treatment, acuity tests and their formulation are given in detail

In a book of this nature, which is essentially an introduction to the fundamentals of the experimental method in psychology, we might have expected the mental tests to have claimed a little more attention. For full details, of course, the books especially devoted to this subject would in any case have to be consulted, but mental tests form an interesting example of the application of the statistical methods in a simple form Statistical matters are frequently a source of terror to those students of experimental psychology who may have approached this subject via the arts rather than the sciences, and are not conversant with mathematics In view of the recent interest in the measurement of the emotions it would have been interesting to have an experimental exercise describing the psycho-galvanometer and its circuit, an arrangement no more complicated than Hipp's chronometer and its appendages These are the only small criticisms we have to make on a book which is likely to remain one of the best handbooks on the subject

THE LANGUAGE AND THOUGHT OF THE CHILD

By JEAN PIAGET, Professor at the University of Neuchâtel and the Institute J J Rousseau, Geneva London· Kegan Paul and Co, Ltd 1926 Pp 246 10*s* 6*d*

WHILE much attention has been paid to the study of the child from the point of view of mental tests and delinquency comparatively few attempts have been made to trace the growth of the young mind in its effective relationships on the one hand and its logic on the other The psycho-analytic school has approached [illegible]ld mind for the purpose of tracing

Library Medical College 7786

part shows the spectral yellow of sodium (589 $\mu\mu$) This arrangement allows the fixing of Rayleigh's equation—that is, by making a variation in the respective proportions of red and green, and the luminosity of the sodium yellow, the two parts of the field may be made the same Dr. Verrey said that this apparatus enabled us not only to detect colour blindness, but also to make a diagnosis of the kind of defect Artificial colours were not so safe for testing as spectral colours

Mr **BUTLER** thanked Dr Verrey in the name of the Section for his valuable paper, and suggested that at a future meeting of the Section it might be well to devote more time to a discussion on the subject of colour vision

An informal discussion on

Ophthalmic Benefit

was opened by Dr **COURTENAY LORD**, secretary to the B M A Ophthalmic Committee, who pointed out the importance of ophthalmic surgeons doing everything in their power to make the scheme a success In the discussion that followed it was mentioned that many panel practitioners had the impression—which is quite erroneous—that all insured patients are now entitled to such benefit As a matter of fact only a minority of the approved societies have as yet adopted it Some of the largest societies appear to refer to ophthalmic surgeons only cases with which opticians have had some difficulty

Reviews and Notices of Books.

MODERN MEDICINE

Its Theory and Practice Edited by Sir **WILLIAM OSLER**, Bart, M D, F R S Third edition, thoroughly revised Re-edited by **THOMAS MCCRAE**, M D, assisted by **ELMER FUNK**, M D Vol III.: Diseases of Metabolism, Diseases of the Digestive System London Henry Kimpton 1926 Pp 1052 Set of six volumes and index, £12 12*s*

THIS volume of the third edition of "Modern Medicine" is of especial importance, since it incorporates the insulin treatment of diabetes The whole section on metabolism, occupying over 200 pages, is well up to date A long section on the physiology of metabolism, written by Dr Eugene Du Bois, points the way to the correct interpretation of the diseases coming in this category Starting from a survey of basal metabolism, Dr Du Bois proceeds to consider the digestion of carbohydrates, fats, and proteins in the light of recent work, as well as that of alcohol and the minerals Vitamins are also dealt with, and a useful table of vitamin distribution in foodstuffs is given Two other tables deserve mention · one based on over 1000 cases proves that basal metabolism is only disturbed in four or five diseases; the second gives a list of the composition and caloric value of every imaginable article of diet The succeeding article on diabetes mellitus and insipidus is contributed by Dr Thomas Futcher, who, in considering the ætiology of the former disease, makes a wide survey of the factors depending on disturbances of the endocrine glands When writing on insulin, he insists that proper dieting remains the basis of therapy whether insulin be used or not; he distinguishes between diabetic coma and collapse, and describes the treatment of the former An excellent article on gout is contributed by the same author The last chapter in this section, on obesity, written by Dr James Anders, is full of interest

The larger section on digestive diseases is prefaced by a discussion on the whole subject by Dr Charles Stockton, who makes an attempt to give a synthetic picture of the factors pertaining to all digestive processes Next Dr D Riesman and Dr H Mohler contribute a well-illustrated article on the mouth and salivary glands Dr. Chevalier Jackson and Dr Louis Clerf write with authority on the œsophagus, supplying clear radiograms Dr J Friedenwald, discussing the difficult subject of gastric neuroses, has rejected the older classification into motor, sensory, and secretory neuroses, and has substituted vagotonic and sympatheticotonic groups, into which, however, not all the neuroses he mentions seem to fit very well, for instance, bulimia (increased hunger) and acoria (absence of sense of satiety) find themselves on opposite sides of the division Passing on to the sections on organic disease, Dr C Martin and Dr C Sutherland have written on the stomach, and Dr A. Stengel on the intestines In the former section ætiology receives full notice, the frequency of cancer supervening upon peptic ulcer is not thought to be great The X ray appearances of both ulcer and cancer are described at length In the section on intestine, which is full of well-classified information, the subject of constipation is admirably summarised Dr E J Wood writes on sprue, and emphasises the "strawberry" treatment, other forms of treatment mentioned are parathyroid and calcium, blood transfusion, and yeast vaccine Following this is a weighty article on pancreatic diseases by Dr E L Opie, he goes fully into the symptomatology of pancreatic impairment and acute and chronic forms of pancreatic disease Dr Opie states that diabetes mellitus not infrequently occurs with carcinoma of the pancreas, but gives no confirmatory figures of this important assertion Diseases of the liver, gall-bladder, and biliary ducts are fully dealt with in an article by the late Dr A O J Kelly, which Dr Vincent Lyon has revised . especial reference is made to Sir H Rolleston's work on this subject The normal functions of the liver are first enumerated, then follows a full account of liver functional tests, including the van den Bergh test, next comes an article on jaundice, in which the much discussed theories of its pathogenesis are examined and subsequently the involved subject of non-surgical drainage of the biliary tract, a method dating from 1919, is set forth from both diagnostic and therapeutic points of view This summary of modern work, combined with good descriptions of the many diseases involved, combine to make up a section of exceptional interest Diseases of the peritoneum are presented by Sir Humphry Rolleston in a masterly article of 90 pages; in considering acute diffuse peritonitis he gives a prominent place to its bacteriology The various anatomical types of subphrenic abscess are most helpfully classified The volume ends with a concise article on Glénard's disease by Dr Thomas Brown, who gives careful accounts of theories of pathogenesis, especially that of Keith, and stresses prophylaxis

The keynote of this whole volume, consisting as it does of so many and various articles is disordered physiology, this aspect of medicine marks at once the road to future advance and the barrier against ephemeral methods of study It is certain that any reader perusing these pages with a view to advancing his knowledge will at the same time revive in his memory the physiological training which is rapidly becoming what it always promised to be—the ground work of scientific medicine

MEDICINE AND POOR-LAW REFORM

IF there are any who remain unconvinced of the need for reform of Poor-law administration the facts contained in the latest annual report of the Ministry of Health[1] should provide them with food for thought Reviewing the experiences of the year ended March 31st last, the report comments on certain obvious inequalities in the standards of relief adopted by different boards of guardians and the apparent laxity of administration exhibited by some of these bodies Possibly the increase in the average weekly number in receipt of relief from 1,113,015, or 287 per 10,000 of the population in 1924–25, to 1,207,302, or 312 per 10,000 in 1925–26, may be sufficiently explained by the present trade depression, but some of the statements made in the report suggest that there may be other causes For instance, in reference to the absence of precautions in the relief of able-bodied persons, the guarded conclusion is reached that "it cannot be regarded as proved that unnecessary expenditure of the ratepayers' money is not being incurred," and (more emphatically) "it is beyond question that in certain unions laxity of administration has led to substantial additions both in the number of recipients of relief and in the burden of cost placed on the ratepayers" Again, in relation to an increase during the year from three to twelve in the number of unions in which the persons relieved exceeded a proportion of 1 in 10 of the population, the following comment is made · "It is difficult to avoid the view that the policy and method of administration adopted by one or more boards of guardians in each of these areas has had a substantial effect upon the numbers relieved in the unions adjacent to their own" There is much more to the same effect, but we have probably quoted enough to show that the position is so unsatisfactory in some areas that even official language cannot disguise the view taken by those who have all the facts before them Our readers are aware that the case of West Ham, which is described in the report, has since been the subject of action by the Ministry

The prolonged consideration and wide publicity which the subject of Poor-law reform has received since the Royal Commission on the Poor-laws reported in 1909, has left the present system with few supporters Even the guardians themselves are not content with things as they are and, in response to the Minister's proposals for reform forwarded to boards of guardians with a covering circular (Circular 658) on Jan 2nd 1926, the Association of Poor-law Unions has not hesitated to make counter-proposals of a fundamental if less drastic character The actions of bodies such as the West Ham Board of Guardians are largely an attempt to force on the country a measure of reform which appears to them to be desirable It is when we come to consider details of method that the greatest diversity of opinion is revealed The essential feature of the Minister's scheme is the transference of practically every function of the Poor-law unions to county and county borough councils But the proposals go further Modern developments of the health services have been more or less haphazard, and indeed the Ministry of Health Act, 1919, was generally regarded as a first step toward a much-needed coördination, both centrally and locally, of the activities of the various bodies responsible for communal health in its various aspects The present system of local government and the inequality of public health districts, both as regards area, population, and rateable value, have been the stumbling-block The forms, too, which extension of medical benefit under the Insurance Acts and alterations of its administration should take have had a bearing on the subject. While the deliberations of the Royal Commission on National Insurance have resulted in some concrete recommendations,[2] such as the early abolition of insurance committees and the absorption of their functions by the appropriate local authorities, it cannot be said that the first report of the Royal Commission on Local Government[3] contains anything which clarifies the local government atmosphere The problem of local government areas is fundamental but fraught with innumerable difficulties both of a sentimental and practical nature, not the least of which are the various vested interests involved

The proposals of the Minister for bringing about the desired coördination of the health services along with the transference of Poor-law and insurance functions to county councils are simple The non-county borough and district councils are to be left in being, but to be placed more strictly under the jurisdiction of the county council Under these conditions some of the newly transferred responsibilities may be delegated to the former, but largely, it would appear, at the option of the latter This can hardly be a permanent solution of the problem of local government It fails to face the need for a radical re-casting of public health areas, although it appears to be sufficiently drastic to call forth vigorous opposition from those affected.[4] The attitude of medical officers of health to the proposals, depending on the type of governing body they serve, is also reflected in a recent discussion held at the Public Health Section of the annual meeting of the British Medical Association in Nottingham, of which a notice is included in this issue (p 495) Plainly the official policy has failed to steer clear of controversy and yet the fundamental difficulty of local government areas remains untouched. There are urban districts like Willesden and the Rhondda which exceed many county boroughs in population and are not inferior in administration There are urban and rural districts too small to carry any responsibility involving the expenditure which the modern health services entail and whose councillors exhibit a narrow parochial outlook There are whole rural counties, particularly in Wales, so small and impoverished that they are scarcely fit to form public health units[5] Although the Royal Commission on Local Government has failed to furnish the Minister with some practical solution of this question, something may be learned from the success of the Scottish local government system in rural districts While, then proposals, such as the transference to county councils of the responsibility for the administration of financial relief, may give rise to some apprehension, we are mainly concerned that the medical services under any its instinctual and emotional development, while the anthropologists have sought to bring out the analogy between primitive mentality and the thought of the child Prof Piaget's book therefore fills a gap in the study of the subject of the mental life of the child Taking groups of children under the age of seven years in ordinary kindergarten surroundings, he made exhaustive reports of their conversations as they played, drew and wrote together, believing themselves to be unobserved He concludes statistically that the speech of a child is in its early stages a passage from echolalia to monologue, and from thence passes to the collective monologue At this stage the language of the child is practically the verbalisation of actions, where words possess a "magic" in that they partake of the nature of the object named

[5] THE LANCET March 27th 1926, p 669

With contact between one child and another speech begins to be socialised in the form of adapted information, but an adaptation which consists of the clash of a series of affirmations which are bound together by no logical nexus or "because" Each child lives in its own world of verbalised actions, which may or may not correspond with the world of its fellows Language therefore at this level is almost entirely egocentric Not till the age of seven does true reflective thought make its appearance with the appreciation of cause and effect as the law governing ground and consequence Subjective synthesis and schematisation precedes any real appreciation of objective relationships Remarks are made as justifications of immediate acts, and thoughts proceed by the use of immediate analogies, imaginary reasoning, radiation of one schema into another, and by symbolism Thought in other words is syncretic—that is, wholes are understood before the parts are analysed—and understanding of the parts takes place rightly or wrongly only as a function of the general scheme Understanding between children only takes place in so far as there is contact between two identical wholes which the children may happen to share If they wish to express to one another the discovered relationship between two phenomena, they will say that "this goes with that," a dynamic relationship which may carry with it the larval appreciation of causality

A chapter entitled "The Child's Questions" is of interest in that it deals in a scientific way with the parent most amusing and bewildering task of the parent It goes to prove that the child's questions are mainly concerned with human actions, and are strongly affective At first the questions are related to the resistances to desire met with by the child in its observation of things and people These are the "why's" of justification The meaning for everything has two sides, the explicatory and the implicatory functions respectively; the one turns to the outside world, the other to the inner world to analyse the intuitions and their relations This inner analysis runs counter to the phantasies of the child and thus the two functions have to be fused This final discussion of the book is most difficult in that the affective element of the mind is not sufficiently dealt with, for it is the harnessing of affectivity by the reins of logic that marks the transition from egocentricity to the acceptance of the order of external reality

FUNCTIONAL NERVOUS DISORDERS

Their Pathology, Diagnosis and Treatment By PAUL BOUSFIELD, M R C S, L R C P London William Heinemann 1926 Pp ix +212 6s

IT is not easy to see for what particular circle of readers this book is written It is too compressed to be of value to the beginner, and the specialist will find nothing here that has not already been written If the object of the book is to convince those who are not adherents of the psycho-analytic school of the therapeutic merits of this school, detailed case proof should have been collected and submitted bare assertion carries little weight at this stage of the subject The opening chapters of the book deal with psychological foundations and are not very satisfactory One is devoted to a vague something called "tension," which is never defined, and is followed by another on the unconscious, which contains no objective proof of the reality of unconscious mental processes When he comes to the classification and treatment of the neuroses the author becomes involved in difficulties He makes a strenuous effort to follow faithfully the official classification of Freud, but it is clear that Dr Bousfield does not find it a helpful classification or even one which can be made to accord with clinical fact While he never fails to repeat that analysis is necessary for each condition it would seem that in actual practice he obtains most of his results from different forms of persuasion In certain conditions he relies on the use of trickery and deception (pp 50, 60, and 91)

There is a useful chapter on certain psycho-physical conditions, such as asthma and the disorders of menstruation In the latter conditions the author shows how much these troubles are due to faulty ideas held in consciousness, ideas whose existence depends on education and on the prevalent opinion that to be menstruating is to be "unwell" The book concludes with a chapter of five pages on insanity in which the remarkable doctrine is laid down that dementia præcox and paranoia are in their early stages amenable to analytic treatment

---

GUY DE MAUPASSANT

By ROBERT HARBOROUGH SHERARD London T Werner Laurie Ltd 1926 Pp 399 21s

THE author qualifies his book on the title-page, describing it as dealing with the life-work and evil fate of its subject, whom he designates "Gentilhomme de Lettres," while he asserts that he has written "*l'humble verite*" This was the sub-title of Maupassant's greatest long novel, and Maupassant justified it by supreme accuracy of observation, and by a personal detachment which is not evident in Mr Sherard's writing He obviously knows very much about Maupassant, and has made up his mind about him, while he has laid under contribution the opinion of Maupassant's contemporaries, personal friends, and especially his valet cook The book is written with unstinted admiration for the great French story teller, and contains some sound criticisms of literature, but the medical interest, which presumably we are invited to notice, is slight The details given of Maupassant's breakdown do not make material for safe medical comment as they are too vague We get a good idea of Maupassant's physical and mental make-up, but no facts which explain successfully how, when and why the disastrous breakdown came

---

MALARIA

Paludisme By E MARCHOUX, Professor à l'Institut Pasteur Nouveau Traité de Médecine et de Thérapeutique No 5 Paris J B Baillière et Fils 1926 Pp 366

THE last few years have witnessed a remarkable activity in the production of monographs on malaria, by no means the least complete or exhaustive is the one under review In an unpretentious volume of moderate compass Prof Marchoux has managed to collect most of the current knowledge on this capacious subject The historical survey with which the monograph opens is especially to be commended, though the comparatively insignificant role assigned to Manson will be deplored by those who know how large a part he played in the earlier investigations on malaria The general account of the morphology and development of the malaria parasite, both in the blood of man and in the invertebrate host is full and accurate, though the coloured figures of these hæmatozoa are rather crude The clinical, therapeutic, and preventive sections of this work compare favourably with any we have seen Prof Marchoux's work is a valuable addition to the series of monographs of which it forms the fifth volume regional adenitis, and slight changes in the central nervous system. Histologically, the brain and cord showed the same peculiarities as the case noted ten years previously. Other cases were now quickly recognised—one in a man of 21 and the rest in girls of 7, 12, 15 and 22 respectively. All these patients except one girl died in the course of an acute attack of encephalo-myelitis complicated by broncho-pneumonia. In the exceptional case the encephalo-myelitis was in process of healing, death being due to pneumonia and septicæmia following severe hæmorrhagic inflammation of the paralysed urinary bladder. The infiltrations in the acute cases resemble in general those of non-purulent inflammations of the central nervous system. The chief histological characteristics are the number and size of zones of extra-adventitial perivascular infiltration in comparison to the development and size of adventitial vascular sleeves: the obvious perivascular distribution of the infiltrations: the conspicuous zones of softening with relatively little cellular infiltration that surround vessels in the white matter: the large extent to which the white matter is involved, although the involvement of grey matter is actually greater; the extensive involvement of both cerebral cortex and spinal cord: and the maximal incidence upon lumbar and upper sacral cord and pons. The close similarity in the type and incidence of the inflammation in all cases is notable, and the authors draw special attention to the peculiar zones of perivascular softening in the white matter. The lesions in the subacute case suggest the healing stage of those described. They have the same general distribution but are smaller and fewer, the foci of intenser acute inflammation having commenced to scar, whilst the less intense, more diffuse infiltrations have apparently undergone complete resolution.

Elaborate efforts have evidently been made to obtain positive proof of the connexion between vaccination and the conditions depicted, or, failing this, to exclude any other possible ætiology. Investigation of the possible path of infection gave negative results; no direct evidence was found, in sections of the brachial plexus, of any extension of inflammation along nerves from the vaccinated areas to the spinal cord. Close examination of the vaccinated areas and regional glands yielded but little information since the histological changes appeared to be essentially similar to those in a control case, a recently vaccinated boy killed in an accident. But though the path of infection cannot be traced, the authors would appear to have ample justification for concluding, in view of the close resemblance between the clinical histories, the uniformity of the pathological findings, and the absence of similar cases independent of vaccination, that vaccination was a definite causal factor and no chance coincidence. Death in six cases occurred between the fourteenth and the eighteenth days after vaccination. In the remaining case consciousness was regained on the eighteenth day but the patient remained drowsy and died on the twenty-ninth day after vaccination. The periods after vaccination at which consciousness was lost, at which alterations in the pupils, rigidity and paralysis of limbs and paralysis of the bladder were observed, at which death occurred or consciousness was regained show close correspondence except in one case where paralysis of the bladder and loss of reflexes were observed as early as the fourth day after vaccination. [illegible] cases independent of vaccination were not observed at the same nor any other time. The authors give cogent reasons against the assumption that the post-vaccinal cases described by them and by workers abroad are merely examples of either poliomyelitis or encephalitis lethargica in which vaccination was an immaterial accident. Histologically, the inflammation in ordinary cases of poliomyelitis differs conspicuously from that following vaccination, whereas encephalitis lethargica differs from post-vaccinal encephalitis in extent of distribution. In Holland eight cases[1] occurred in 1925 during those months when encephalitis lethargica was epidemic, and the suggestion was made that the vaccination may have provoked a latent encephalitis lethargica. Prof. TURNBULL and Prof. MCINTOSH considers this unlikely, and note that if post-vaccinal encephalo-myelitis is caused by the virus of encephalitis lethargica, then the resulting reaction has been so greatly altered by the vaccination as to give a distinct histological picture. The distribution of lesions in 40 cases of encephalitis lethargica examined by them, though extremely variable, is always less extensive than that of the lesions in post-vaccinal encephalo-myelitis, and in no case did they find the zones of softening round the vessels of the white matter which is characteristic of the last-named condition. The fact that the virus of vaccinia is closely allied to, if not identical with, the virus of variola has led them to search the literature for evidence of non-pyogenic inflammations of the brain and spinal cord complicating small-pox, and they have found a considerable number of cases of an apparently specific encephalomyelitis clinically associated with this disease.

The importance of these investigations needs no emphasis. The authors state that they informed the Ministry of Health in December, 1922, of the facts observed—that is, as soon as their tentative interpretation of the findings in the first case were to some extent confirmed by the advent of the second. Doubtless these early observations were the genesis of the committee appointed by the Minister, to whom reports on the histological and experimental investigations here described were sent in January, 1924. It remains for practitioners to be alert to detect and report anything whatever which may seem to bear upon an interesting problem in epidemiology.

◆

MORE ABOUT MILK.

EVERY good woman knows that milk is an incomparable food, and that glasses of hot milk at 11, 3 and 9 are, with patience, all that is necessary to complete many convalescences. Five years ago the sauciness of school-boys, for whom Dr. E. V. MCCOLLUM had secured an extra tot of daily milk, was causing some stir among the school-teachers in Baltimore, and Dr. CORRY MANN has recently noticed the same effect and has confirmed the material advantages of milk for children by the colder arbitrament of the balance and Dr. MAJOR GREENWOOD'S statistics. Of the reasons for these things we still have much to learn. The nutritive value of different proteids urgently needs further elucidation: there is no doubt a good deal of importance that we do not know about dietetic mixtures of proteids, fats, and carbohydrates: no one seems much concerned to discover why milk is as good for useful middle-aged persons as it is for infants who can only just live. Meanwhile our information about the vitamins of milk and their relation to children's diets goes on increasing splendidly. It is now recognised that there are two new scheme should have conditions which will allow of their highest development, in the scientific sense, without abuse of public money and without encroaching on the legitimate interests of private practitioners Reform of the Poor-law ought to afford an opportunity for providing such conditions With a few outstanding exceptions Poor-law guardians have not sought or availed themselves to any extent of medical advice in their deliberations Their hospital administration has been the function of workhouse masters and untrained matrons, with the result that medical and nursing personnel and scientific equipment, which are the main justification for the existence of hospitals, have been neglected Their out-patient provision has been primitive While a striking alteration of attitude to the sick pauper has taken place in the last 25 years, admission to the benefits of the medical services of the Poor-law is still accompanied by a ritual humiliating both to patient and medical officer Thus we have the spectacle of large hospital blocks, ill-arranged from the medical standpoint, standing with many vacant beds, while the voluntary hospital waiting-lists have got completely out of control Transference of the medical functions of the Poor-law to county and county borough councils should bring a change of policy, for the latter bodies are accustomed to receive and to follow medical advice on medical matters The administration of medical benefit, too, by the new local health authorities should pave the way to a measure of uniformity in the domiciliary care of the sick-poor and the insured, while the control of hospitals by these authorities should facilitate extension of the medical services covered by the Insurance Acts Finally, the rapidly developing provision made by education and health authorities for mothers and children and for those suffering from such diseases as tuberculosis and venereal diseases, which have hitherto shown a tendency to diverge from the ordinary run of medical work, should now be brought into line with general medical and hospital practice

---

[1] [illegible]

This brings up again the question of the optimum size of area In his address to medical officers of health at the recent Jubilee Congress of the Royal Sanitary Institute Dr G F BUCHAN entered a plea for the retention of all units with a population of 50 000 or over as autonomous authorities with complete control of local medical services, a proposal which would practically abolish the health activities of county councils The implication is that an area capable of maintaining one whole-time medical officer is big enough for efficiency Few sanitarians will go as far as this However undesirable early specialisation may be, the variety and difficulty of modern public health work make it unavoidable in branches of work such as the diagnosis and management of mental defectives, the care of crippled children, the diagnosis and treatment of ear, nose, throat, and eye defects in children, and the care of pregnant women A high standard in all these directions can hardly be attained by an officer whose time is taken up with administrative and advisory duties From this point of view there is much to be said for the county and county borough as units, provided that it is made easier for the larger urban districts to attain the county borough status and so escape irksome supervision by the county authority. On the other hand, it may be argued that the clinical services are properly the function of part-time specialists In that case there is hardly need for an area with a population of 50 000 to maintain a whole-time medical officer at all Moreover, the administration of services worked by a part-time staff is notoriously difficult and entails special knowledge on the part of the administrator Such officers ought to command salaries on a scale which only the larger authorities can afford, and therefore the case for the county and county borough unit is not weakened. But if the present public health areas are to remain the Ministry of Health might at least take courage to acquire compulsory powers for bringing the medical officers of small district councils definitely on to the county health staff, a policy pursued by persuasive methods for many years Opportunity should be taken to sever as far as possible from the work of health departments the provision of assistance either in money or in kind, such as free milk and meals, or financial aid to the blind. All kinds of assistance would then be coördinated under some committee of the new authority not directly concerned with medical matters

◆

ENCEPHALO-MYELITIS FOLLOWING VACCINATION

IN April last we were asked to give publicity to the formation under the auspices of the Ministry of Health, of a committee to investigate cases of encephalitis directly following vaccination Practitioners observing such cases are requested to communicate with Dr J R HUTCHINSON, the secretary of the committee, and, in the event of a fatal issue, to forward to him material preserved in special media It is of the utmost public importance that these investigations should be prosecuted, since, though this sequel to vaccination appears to be extremely rare, nevertheless during the last 14 years Prof H M TURNBULL and Prof JAMES MCINTOSH, working at the London and Middlesex Hospitals, have been able to collect seven cases of encephalo myelitis in which they assert, " there can be no doubt that vaccination was a definite causal factor " An exhaustive account of these cases in the current number of the *British Journal of Experimental Pathology* includes summaries of clinical histories and necropsies, and descriptions of the pathological changes, gross and minute, in the central nervous system as well as in the vaccinated areas, regional lymphatic glands, and other tissues Beautifully clear drawings illustrate the histological lesions found in cortex, medulla pons, and in various sections of the spinal cord at lower levels The evidence of ætiology derived from clinical and histological manifestations is shown to be strong, and is confirmed by the results of biological experiments made independently by Dr PAUL FILDES and Prof MCINTOSH Inoculations of material from the brain and spinal cord of three of the cases showed the presence of vaccinia virus, no other virus being obtained

The attention of the authors was first drawn to this condition in 1912, when encephalo myelitis was found at necropsy in a lad of 15 who had recently been vaccinated The histological changes in the central nervous system differed in many features from those found in the lesions of the poliomyelitis which was epidemic in the neighbourhood at that time, and in view of the recent demonstration by A MARIE and by C LEVADITI, P HARVIER and S NICOLAU that vaccinia can cause encephalitis in the rabbit, vaccination was considered a possible causal factor Not till ten years later did the opportunity occur to test this possibility in a comparable case In December, 1922, a girl of 9 who came to necropsy with a diagnosis of tuberculous meningitis, had no macroscopic lesions except recent vaccination scabs to keep sandflies alive in captivity and to induce them to feed The optimum temperature for these insects was found to be 28° C Immediately after a full feed of blood the sandfly has a characteristic bloated appearance and becomes sluggish If dissected 24 hours later and the blood examined, the parasite will be found to have increased in size and to contain a prominent vacuole. Seventy-two hours after the initial feed there are seen elongated free-swimming flagellates which show active signs of multiplication At the end of the third day the parasites are generally diffused throughout the midgut, while subsequently, still actively dividing, they migrate towards the anterior portions of the viscus After the fifth day the insect will have laid its eggs, and a second feed of blood appears to be necessary in order to preserve the life of the sandfly and to assure the further development of the parasites within it The parasites now tend to aggregate into rosettes, and enormous masses composed of many individual rosettes are seen The intensity of infection at the extreme anterior end of the midgut is such that the parasites form a plug blocking up most of the lumen The maximum development takes place by the seventh or eighth day, the flagellate forms are actively motile amongst the still undigested blood in the insect's stomach and eventually migrate to the pharynx, the blockage in this case is such as to recall the obstruction of the œsophagus by plague bacilli During this period of multiplication free flagellate forms are being set free from the clot and these wander into the buccal cavity In its mode of development in the sandfly *Herpetomonas donovani* differs materially in one respect only from *H ctenocephali* which occurs as a natural parasitic infection in the dog-flea *Ctenocephalus canis*, in the latter a continuous process of proliferation takes place posteriorly towards the hindgut in contradistinction to the *anterior* development of *H donovani* In this respect *H donovani* is an aberrant species in its behaviour in the insect host It is evident that even in the most heavily infected flies the parasite by the fifth day of its development in the sandfly will have only commenced to invade the pharynx, and until more precise knowledge of the mechanism of the action of the mouth parts of the sandfly in the act of biting has been accumulated, it will be impossible to say whether the parasites present in the pharynx only are capable of being transferred to the wound made by the mouth parts It is probable, however, that the parasite cannot be transferred to its new host until a buccal infection has occurred, and this stage of development is only reached after the second feed of the sandfly, so that transmission from insect to vertebrate host can only occur at the third feed Until much more experimental work has been performed on these lines the authors justifiably reserve their final opinion that the sandfly has been proved to be the true vector of kala-azar but their work has already placed the question upon a new basis

LEAD POISONING FROM FOOD

THE story is told in the *Presse Medicale*[1] of an outbreak of lead poisoning which commenced at Vidin in Bulgaria during April 1923, and only terminated when its origin was detected five months later By this time there had been 314 cases occurring in 153 families with three deaths while several other deaths occurred among those poisoned as a result of other disorders considered to have been brought on or at least accentuated by the lead absorbed, notably one case of cancer of the rectum in a woman aged 28 is attributed to this cause The number of cases ranks the epidemic with others such as have followed upon accidentally mixing of white lead with flour, from drinking plumbo solvent water by the royal household at Versailles in the eighteenth century and from Loch Katrine in Glasgow at the end of the nineteenth century, and the 350 cases at Saint-Georges-sur-Eure in 1865 The signs and symptoms appear to have been quite typical, the blue line was present in 99 per cent. of cases, lead colic was frequent and affections of the nervous system, with 3 cases (1 fatal) of encephalopathy Nephritis and wrist-drop, symptoms of chronic lead poisoning, were not observed The source of the poisoning was found to be adulterated red pepper This pepper, prepared from capsicum fruit is much used in Hungary and Bulgaria, and it is often adulterated with such things as maize or vetch flour, sawdust, iron filings or brick dust; but on this occasion analysis revealed the presence of 20 5 per cent of red lead and 4 1 per cent of sand, while very small amounts of true pepper were found This fraudulent "red pepper" was placed on the market by only one firm, and inhabitants who bought their red pepper elsewhere or made it themselves escaped Most of the cases followed the ingestion of a number of small doses, a teaspoonful of pepper serving two to four persons for several days · but one case followed a single dose of two teaspoonfuls of "pepper," containing about 6 gr of red lead, taken at one meal the case recovered

YAWS IN KENYA

IN the many tropical regions where yaws afflicts humanity its importance lies not so much in any mortality directly caused by it, as in the very large numbers who may be affected and the great amount of physical disability it produces It is often the principal factor to be dealt with when attempting to raise the general standard of health Each yaws patient needs individual treatment, and must be induced to come forward to receive it It may be taken as the rule, however, that the aboriginal of the tropics everywhere has not been attracted to European medicine and sanitation He has preferred his own ancestral ways, and often enough in the past it has made no difference Even Manson, whom Blanchard dubbed "Father of the modern science of tropical medicine," could not win the intelligent Amoy Chinaman's confidence in his powers as physician, except by the dramatic results of his surgery This readiness to accept and seek the European surgeon, while disdaining the European physician, has been the common experience of practitioners in the tropics dealing with indigenous populations Then came arsenobenzol drugs and their use in yaws The resulting rapid cure of the loathsome skin lesions was as dramatic as anything surgery could show The fame of this treatment, wherever tried brought about a change in the mind of the native in favour of European medicine His repellent indifference, apparently so complete and ineradicable, to the horrible condition of his own and his fellow's yaw-stricken bodies is now shown to have been admirably philosophical and truly courteous, for, as soon as a cure is known, because seen, all want to be cured and come for cure But the arsenobenzol drugs are costly, medical officers in the tropics are comparatively rare and in the eyes of administrations, expensive, and there is the difficulty of delegating a skilled procedure such as intravenous injection to partially trained native assistants Happily, bismuth now proves to be as effective a remedy as arsenobenzol it is very much cheaper and its subcutaneous or intramuscular injection can be entrusted safely to native *assistants*

Probably in few parts of the world is there such a mass of material available for the study of yaws as in Tropical Africa Dr J O Shircore recently wrote[1] of 113,000 cases of yaws treated in Tanganyika Territory Dr C J Callanan[2] describes his campaign against yaws in a heavily infected area lying in the shadow of Mount Kenya The natives there believe that yaws has been amongst them from time immemorial, it is unusual to find one who has not had the disease at some period of his life An idea of its prevalence is given by the fact that over 24 000 cases vitamins (at least) which are associated with fats and have to do with growth: A, which promotes growth and prevents xerophthalmia and the keratinisation of mucous membranes; D, which promotes growth and prevents rickets, and for which exposure to ultra-violet light is a tolerable substitute. The differentiation of these two factors has naturally invalidated a good deal of earlier work in which they were confused, and it has complicated the technique of experimental titration; at the same time it seems to afford a basis for the reconciliation of clinical and experimental results which seemed inconsistent. The dissection and measurement of the two factors in cow's milk has lately been achieved[1] in a very interesting way by Dr. HARRIETTE CHICK and Miss M. H. ROSCOE at the Lister Institute, in an elaboration of Miss E. M. LUCE's work on the effects of diet and sunlight on the vitamin content of milk. Without going into the detail of the technique, the whole sums up to the conclusion that the content of the milk in vitamin A depends on the food of the cow, and is not influenced by exposure of the animal to sunlight, while its content in vitamin D is determined mainly by the degree of insolation. Fresh green food given in a dark stall results in milk with a maximum amount of A, which is not increased by turning the animal out to pasture; A is at its minimum on a diet of cereals and roots. But the power of the milk to prevent rickets depends chiefly on whether the cow was indoors or outside, though green food appeared to also have some beneficial effect. The best milk, therefore, is obtained when the cow is pasture-fed in summer, and the virtues of such milk may be preserved by making it into butter and keeping it in cold store. The results are another illustration of how the modern knowledge of accessory food factors explains the empirical methods of common human experience, and of how necessary this knowledge is to correct the ingenuity which devises methods of intensive milk production by stall-fed cattle and such-like "scientific" plans. Much milk of this kind is produced, and in the form of butter is widely dispersed; so it is good news to learn[2] that this year is providing a record catch of fish and cod-liver oil.

OLEOTHORAX

A RECENT annotation[3] on oil replacement in pleural effusion was written just before the publication[4] of more precise details of its use by the originator, Dr. A. Bernou. His work suggests that the chief value of the operation lies in its use as a safe means of replacing purulent tuberculous effusions whether primary or secondary to pneumothorax, and that it is worthy of trial before the more serious open operations are considered. Dr. Bernou does not write very hopefully of the value of oleothorax in simple acute pyogenic empyemata. One of the advantages claimed for the method is that the oil used for the purpose, known as gomenol, does not produce adhesions. This substance, as might be supposed, does not act directly upon the tubercle bacillus; its effect is rather to produce dilatation of the blood capillaries of the serous membrane and subsequent leucocytosis. Proteolytic and lipolytic action follow, and the action is akin to that which takes place when a modifying fluid is injected into a cold abscess. The rate of absorption varies according to the type of case for which oil replacement is used. In some cases rapid absorption takes place in a few days; in other cases practically no absorption has resulted after many weeks, thereby effectively maintaining the collapse of the lung. From the records so far published the operation appears more useful for the replacement of purulent fluids than for serous effusions.

Annotations.

"Ne quid nimis."

HOSPITAL SATURDAY

TO-DAY is "Hospital Saturday" for the vast agglomeration of population which we call London. It stands by no means alone, for there are half a hundred other Hospital Saturdays in great towns and small. Nor is it the oldest. It dates from 1873, but the example was set to London ten years earlier, appropriately enough, by Walsall, which subsequently became famous as the scene of the devoted hospital labours of Sister Dora. Liverpool appears to have come next, in 1870, and even Maidstone was 12 months ahead of the capital. But it was inevitable that when once London set its hand to the work it should take the lead and keep it. Coming into being in quick succession to the Metropolitan Hospital Sunday Fund, which was founded a few months before it, the new movement, though supplementary rather than competitive, progressed slowly during the first few years. Since everybody does not go to church regularly it was realised that a collection limited to one Sunday in the year left a large proportion of the people untouched. The street collections, which were in favour in the early days, were eventually discontinued in consequence of the steady development of the more systematic and more business-like arrangement of week-to-week collections in workshops and business houses. The Fund suffered a set-back when the National Insurance Act came into being, but that was only temporary, and it now raises more than £100,000 a year. During the 53 years of its existence it has distributed close upon a quarter of a million of money among general, special, and cottage hospitals, dispensaries, convalescent homes, and nursing institutions, and in help to individual cases. This last is by no means the least valuable development of the Fund's work. Tens of thousands of small benefits are granted every year to cases in which timely assistance, of comparatively small individual cost, prevents bad from becoming worse. Surgical appliances, in which we include spectacles, are provided or help given towards their provision for thousands of applicants, and the annual amount of dental assistance grows formidable, though applicants, in the mass, contribute extensively to the cost of this highly important department of surgery. Convalescents are sent to homes, either directly or through the hospitals, entirely or partly at the cost of the Fund which, in many admirable ways, supplements the work of the institutions to which it makes such large cash contributions. Hospital Saturday may, in the main, appeal to a different class from that which is touched by Hospital Sunday, but the appeal is willingly and handsomely met with results which indicate once more the extreme value of system and regularity where money has to be raised for charitable purposes. Thousands of people setting aside no more than a penny a week each, are certain, in the end, to raise far more money than hundreds who are badgered into writing an occasional cheque. The systematic funds, of which there are now very many all over the country, are saving the voluntary hospitals from the perils that, not so long ago, menaced them so gravely.

THE LIFE-CYCLE OF KALA-AZAR

LAST year S. R. Christophers, H. E. Shortt, and P. J. Barraud described what they believed to be the life-cycle of the parasite of kala-azar in the sandfly (*Phlebotomus argentipes*), but their observations were hampered by a shortage of material. In a recent number of the *Indian Journal of Medical Research* (vol. xiii., No. 4, April 19th) these observations have been confirmed and amplified by Shortt, Barraud, and A. C. Craighead. It is no easy task in regard to the lives of those in whom the circumference of the abdomen exceeds that of the chest But even here a hereditary tendency to longevity is the ruling factor, for corpulent descendants of longer-lived parents have a normal expectation of life. Assured persons who are under weight and whose parents died from lung disease under 70 years of age are more liable to die during the age-period 15–28, their excess of mortality being 30 per cent. On the average the risks of the underweight class are not increased : those who have had no lung disease in their family show a diminished mortality Short-livedness is frequently due to arterio-sclerosis or tuberculosis. Mollwos and Florschütz, working with material derived from the Lübeck Life and Gotha Assurance Societies respectively are thought by Dr Ullmann to have established how great a rôle heredity and a feebler constitution play in the ætiology of tuberculosis The tuberculous who have a family history of tuberculosis do not do so well as those whose parents died of other diseases. Florschütz suggests that when this untoward result does not occur it is because special care has been taken of the patient on account of his unsatisfactory family history. Comparison of the family history of tuberculous persons possessing tuberculous heredity with a number of controls clearly brings out their less satisfactory constitution

THE HERITABILITY OF INTELLIGENCE.

SIR Francis Galton s demonstration of the tendency for exceptional ability to run in families has become classic, and to it the modern eugenic movement owes its rise Other investigators have confirmed his results but their methods have varied Galton accepted as a criterion of exceptional capacity or genius the attainment of some position of eminence in the world In the latest of these investigations that has come to our notice described in a *Bulletin* of the Eugenics Record Office published by the Carnegie Institute of Washington the cases selected for study are children—49 in all—whose exceptional ability is inferred from the very high scores obtained by them on the Stanford-Binet scale of intelligence tests The investigation was carried out by Miss Grace Allen and her results may be briefly summarised Of the fathers of the gifted children 70 per cent occupied positions of responsibility and power many professional and 25 per cent were engaged in semi-intellectual work Among brothers 52 and 44 per cent were the corresponding figures Brothers and sisters tested by the Stanford scale, with only one exception scored over 100, and only one cousin out of 21 tested scored below 120 Homes were rated according to the scale of the Whittier State School and in practically all cases and in all respects neatness size necessities parental control, scored high Fecundity in the families concerned was low, the fathers were above average age grandparents were long-lived. The children were the offspring of normal gestations and were physically above the average partly attributable no doubt to the fact that 70 per cent were Jewish. Miss Allen does not make any inferences from the statistical facts but the writer of the preface, Prof C. B. Davenport, does not hesitate to interpret the results as further evidence of the heredity of high intelligence It is somewhat doubtful if such an inference is justified when one considers the small number of cases studied and the admittedly incomplete study of the families they came from Putting this objection aside however there is the further question whether one is entitled to assume as most of these investigators do assume, that any scale of intelligence such as the Stanford-Binet really adequately gauges native intelligence Its value in assessing particularly the higher grades of intelligence has been frequently disputed and the work of Dr. Cyril Burt and Mr Hugh Gordon has shown that the results are very considerably influenced by general environment and school training Is it not the fact that even the development of the intelligence itself is much modified by the nature of the environment ? The general fact that a high grade of ability does frequently run in families can scarcely be disputed, but there is still no completely satisfactory evidence to show how much is due to heredity and how much to the exceptional opportunity afforded in a prosperous and a cultured home The ardent eugenist is too ready to assume that the latter is not essential It may be quite true to say, as Prof Davenport does say, that ‘ the children do not have high intelligence merely because they come from prosperous households but surely the prosperous households make some contribution to the growth of the intelligence. Nature must be nurtured.

CHOLECYSTOGRAPHY.

THE discovery by Prof. E. A. Graham and his co-workers that certain phthalein compounds during excretion by the biliary tract were capable of casting opaque shadows has led to extensive application of this phenomenon as a means of taking X ray photographs of the gall-bladder It has stimulated efforts to improve the technique of radiographic methods applied to the gall-bladder, which are reflected in contributions to medical journals of all countries and in keen discussions at medical societies notably at the Section of Medicine of the B M.A. at Nottingham The opaque substances chiefly employed for the purpose have been tetra-halogen compounds of phenolphthalein and both the oral and intravenous channels of administration have been used Although at the B M.A. meeting, reported in our issue of July 31st it was stated that there had been no death recorded following the intravenous employment of these dyes, since that date a fatal case has been brought to our notice, and it appears expedient to direct attention once more to certain difficulties and risks which face those who are using the method. In the first place it must be recalled that several substances are on the market. Both tetra-iodo and tetra-bromophenolphthalein are in use ; further, in some preparations the halogen atoms are linked to the phenol portion of the molecule and in others to the phthalein As these compounds differ from one another in toxicity both towards the general organism and the local tissues, the problem of selection is not an easy one in the absence of precise guidance Moreover, the fact that they are all extremely unstable makes it difficult to obtain reliable solutions for intravenous use without the assistance of a skilled chemist.

In a recent article in THE LANCET[1] T Izod Bennett, Alan Moncrieff and F. G Nicholas strongly advocated the employment of the oral route of administration : they stated that toxic effects had never given them anxiety and their results appear to have been excellent. On the other hand, they in common with others using this route had had considerable difficulty in finding a capsule to hold the dye which would neither allow it to be liberated in the stomach nor to pass unchanged into the cæcum. If liberated above the pylorus an insoluble substance is formed with the gastric hydrochloric acid and violent vomiting may occur . if, on the other hand, the dye passes into the cæcum there will be no absorption and hence no gall-bladder shadow can be seen If however, a capsule or covering is secured which is digested only in the small intestine the oral route does appear to give results which are quite satisfactory and are obtained without risk. There is on the other hand, little doubt that in general the cholecystograms taken after intravenous injection are clearer and here there can be no doubt in the observer s mind as to whether proper absorption has taken place Since a negative cholecystogram implies disease of the biliary apparatus, it is often of supreme importance for the observer to know that the dye has been fully absorbed into the blood stream Intravenous injection alone can guarantee this If, however such intravenous injections are going to lead to the production of local thrombo-phlebitis owing to inexpert use or if the fatality mentioned above which was were treated in 1922–24 Novarsenobillon injections had been used in the beginning, and two injections, intravenous or intramuscular, usually abolish all outward signs of the disease, though it cannot yet be decided if they produce permanent cure Early in 1923 treatment by intramuscular injection of sodium-potassium-bismuth-tartrate was introduced, and this drug has proved very effective It is made in the Colony, and the cost of materials used in its preparation works out at 10 doses a penny The doses are ¼ to 3 gr dissolved in the proportion of 1 gr to 1 c cm The salt contains 54 5 per cent bismuth, and dosage is regulated according to age and susceptibility, children up to 2 years old receiving ½ to 1 gr of the salt, those from 2 to 18 years old, 1 to 2 gr, adults, 2 to 3 gr, and aged persons, 1 to 2 gr Children, it was found, tolerated relatively larger doses than adults, while old persons were very susceptible to the poisonous properties of the drug Both potassium and bismuth are depressants of muscle, heart, and nerve tissues, and doses of 5 gr of the salt given to adults caused severe stomatitis, with œdema of cheeks, lips, eyelids, scalp, and sometimes of the neck as well, in one case there were tonic and clonic spasms of limbs, unconsciousness, and low muttering delirium Bismuth produces a stomatitis more readily and more severe in type than does mercury Usually two injections of the salt sufficed to procure rapid healing of the lesions, but here also time alone can show if that is really enough for permanent cure Intravenous injection of tartar emetic had no influence on the disease; and when, later, Castellani's mixture by the mouth was tried, the patients rejected it, for by that time they had no faith in any treatment that did not involve injection by needle As a result of treatment, not a tithe of the disease existing in 1921 could be found in the localities to-day, indeed, the vast majority of patients now come voluntarily from districts outside the area of this yaws campaign

---

[1] THE LANCET, July 3rd p 19

Yaws is definitely neither hereditary nor congenital, and a breach of skin surface is probably necessary for the entry of the virus It is significant that by far the most of primary yaws lesions seen in Kenya were found on the anterior surface of the leg—the part of the body most liable to injury, as, for instance, from thorn and grasses along the narrow single-file native paths The disease is spread by direct contact, or by the feet of non-biting flies, while the bite of an arthropod may be a ready place for the virus carried by some other agency, as, for example, by the scratching or rubbing of infected fingers Cases occurred frequently at 5000 ft altitude and over, but were mostly found in the warmer parts of the district The insanitary conditions of native village life are ideal for the spread of the disease, the people live in small, verminous, ill-lighted, unventilated huts strewn around with garbage There are swarms of flies, and micturition and defæcation are promiscuous in and about the villages Though the average accommoda- is 2 4 persons per hut, cattle, goats, sheep, and fowl are herded every night into them besides the human occupants There is no isolation of the sick, they live in intimate contact with the fit, and eat from the common dish with the pus from their ulcers soiling the floor and the clothing of others Clothing, blankets, and bedding are commonly exchanged The practice of depilation of face and body provides a means of entry and a mode of conveyance of the yaws virus, sometimes the primary yaw appears at the site of mutilation resulting from the drastic unclean methods used in circumcision of the youths and excision of labium minus in the maidens. Yet, in spite of all this, merely treatment of those with surface lesions in breaking repeatedly the chain of contagion, has sufficed to bring about this enormous reduction in the disease No evidence was found in support of those who deny existence of the primary yaw The infection cannot be a venereal one, for the only patients presenting genital primary yaws were children The granulomatous secondary skin eruption had a very definite predilection for moist surfaces, such as muco-cutaneous junctions of mouth, alæ nasi, vulva, and anus It was frequently accompanied by inflammation of joint with or without pyrexia In all cases after the secondary eruption had completely healed, tertiary lesions appeared as irregular ulcerations following breaking down of gumma-like nodules Periostitis and dactylitis occurred, but iritis was not observed Scarring after healing of ulcerations led to contractures, muscle wasting and shortening, a common consequence being great deformity Dr Callanan is convinced from his observations that the terrible destruction of palate and nasal bones and skin of face, known as *gangosa*, was directly due to untreated yaws Many of the yaw cases showed splenic enlargement, but no internal organ other than the spleen was seen to be affected No nervous conditions that could be attributed to yaws were discovered—an interesting observation in view of the persistent reports from Fiji of general paresis and tabes dorsalis attributed there to yaws Dr Callanan deserves congratulation on this record of his careful observations on a great number of individual cases, and the organisation and conduct of the campaign It is a valuable contribution to the literature of yaws, whilst the campaign itself reflects credit on the medical administration of the Colony, and provides an instructive and encouraging example for other countries where yaws is a scourge—even for some others under the British flag and the ægis of the Colonial Office

THE ELEMENTS OF LONGEVITY

THE duration of human life has various aspects, the physician at the bedside, the medical man examining a candidate for life assurance, the referee at the headquarters of the assurance company, all work with a different set of data with somewhat different ends in view The philosophic yet precise consideration of the biology of death constitutes the greater part of the work of the last named, he has a tough proposition to deal with To help him there is the inductive method of clinical medicine, the analogy of animal experiment especially used by Pearl, the somewhat unworked field of life-assurance statistics, the science of heredity, and sundry other possibilities into which Dr Hans Ullmann, of Berlin, goes at some length in one of the recent instalments[1] of Brugsch and Lewy's "Biologie der Person" Dr Ullmann cites Rubner's view that the duration of life of a species depends upon the potential energy acquired from its food, Weismann's theory of potential immortality, the effect of the extent of surface, of internal secretions, of the physico-chemical changes, intoxication with products of metabolism, and the hypotheses of the gradual death of increasing proportion of the cells (Kassowitz) and of the gradual loss of power of function in the cells (Ribbert) Obviously the individual duration of life is influenced by sex, by different environments and diseases by social status and race, by the effect of different dietaries by heredity and pigmentations But Dr Ullmann is impressed by the preponderance of familial influence in consequence of which the individual reacts in a certain way to his environment Belief in the occurrence of familial longevity and short-livedness is now spreading, as may be seen in the work of Mary Beeton and Karl Pearson, L Cuénot, D Westergaard, and A Ploetz W Scheidt, working over A von Lindheim's Austrian material, ascertained that out of 281 eighty-year-olds 102 came from parents of whom one was over 80, and 64 from parents both of whom were over 80 Among the old people in the Jewish almshouses in Vienna in 1908, 41 per cent came from parents both of whom were over 70 years old In all 95 per cent of the old people dealt with by Lindheim were from parents of whom at least one was over 70 years old The author gives the unfavourable experience of 31 American life assurance companies a number of cases gastric lavage will have the effect of temporarily stopping the vomiting and the desired result will thus be obtained ; in other cases it may be necessary to resort to re-feeding after the child has vomited, or it may be found that feeds given by a nasal tube will be retained where feeds taken by the bottle will be vomited A breast-fed baby may be allowed to go to the breast in the normal manner unless it is very collapsed, under which circumstances the mother's milk must be expressed and given in a bottle or by a nasal catheter For the artificially fed child any of the formulæ suggested below in connexion with post-operative feeding may be used

---

[1] Die Biologie der Person ein Handbuch der Allgemeinen und Speziellen Konstitutionslehre Edited by Prof Th Brugsch and Prof F H Lewy Third instalment comprising pp 749–1051 of vol i which it completes Berlin and Vienna Urban and Schwarzenberg 1926 Mk 15

Subcutaneous saline should be administered if the child is dehydrated, and if the efforts at making the infant retain food have been unsuccessful 2 per cent of glucose may be added to the normal saline, but this should be used with caution as it is apt to be painful and may even give rise to suppuration On the day of operation the last feed should be given three to four hours and the stomach washed out one hour before going up to the theatre The child should be warmly clad and the arms and legs bandaged in cotton-wool

Technique

Operation —The exact technique of the operation is a matter to be decided by the surgeon Rammstedt's operation of transperitoneal section of the pyloric sphincter has almost entirely superseded all other forms of operative procedure, although Loreta's method of dilating the pyloric sphincter is still preferred by some surgeons

Post-operative Treatment —Following the operation the patient should be carefully watched to guard against shock The temperature must be taken frequently and hyperpyrexia watched for , should the temperature rise above 102° F an ice-bag may be applied to the head If vomiting occurs after operation it will often be found that a small enema of normal saline will have the effect of stopping it Subcutaneous saline may be necessary, but care should be taken to avoid water-logging the child

Post-operative feeding is of the greatest importance The safest method is to give small feeds frequently , if feeding is pushed enteritis is apt to follow and is the most serious of all complications It must be remembered that the stenosis is now relieved and the intestine, which for some weeks has been unused to receiving more than small quantities of food, is in an unfit state to deal with large amounts No very rapid gain in weight should be looked for in the first two weeks

The ideal food for feeding after operation is unquestionably breast milk If this is not available any of the following formulæ may be used :—

(1) Nestlé's Ideal milk, 5 oz. , dextri-maltose, 1¼ oz , water, 25 oz

(2) Fully peptonised skimmed cow's milk, 2 parts , water, 1 part , sugar, 1 teaspoonful to each 3 oz.

(3) Marriot's skimmed lactic acid milk, prepared as follows Boil 1 pint of skimmed cow's milk for five minutes, remove the scum, replace the fluid lost by boiling with cold boiled water up to 1 pint. Cool thoroughly and add lactic acid (B P) 1 drachm drop by drop, being most careful to stir the milk the whole time that the acid is being added Dextri-maltose in the proportion of 1¼ oz. to the pint should be added while the milk is still warm

The following table may serve as a guide as to the amounts to be fed The first feed is given two hours after operation Feed hourly for 11 hours as follows —

2 feeds glucose 7½ per cent solution 1 dr

3 feeds	Breast milk or milk mixture	½ dr	Boiled water	½ dr
2 "		1 "	"	1 "
1 feed		1½ "	"	1½ "
1 "		2 "	"	2 "
1 "		2½ "	"	2 "

Now feed two-hourly for 25 hours as follows —

1 feed	Breast milk or milk mixture	3 dr	Boiled water	2 dr
2 feeds		4 "	"	2 "
2 "		5 "	"	1 "
3 "		7 "	"	1 "
3 "		1 oz.		
2 "		1 oz. 2 dr		

Following this feed give 1½ oz. 2½-hourly for 12 hours, and then 2 oz 3-hourly for 12 hours After this gradually increase the size of the feeds and reduce their number until the child is being fed six times in the 24 hours

If the child is breast fed it will be put to the breast after the first 36 hours unless the condition is very poor Feed 2½-hourly (3 to 5 minutes at the breast) for 12 hours, then 3-hourly (5 to 7 minutes at the breast) for 12 hours After this gradually increase the length of time at the breast and reduce the number of feedings to six in the 24 hours As soon as the child is put back to the breast the amount of food taken must be regulated by weighing before and after each breast feed

Medical Treatment

The medical treatment of congenital pyloric stenosis is based on the fact that if the condition is left to itself there is a definite tendency towards recovery The pylorus will in time open itself, provided that the child does not die before this has taken place If an attempt at non-operative treatment has been decided on gastric lavage should be started at once

Dietetic Treatment —Breast milk is the ideal food, and every effort should be made to obtain it If the child is breast fed it may be allowed to go to the breast in the normal manner, unless very exhausted, in which case milk expressed from the mother's breast must be used If breast milk is unobtainable thick cereal feeding or feeding with skimmed lactic acid milk may be employed

The principle of thick cereal feeding is to supply the infant with the maximum amount of nourishment he can conveniently assimilate and to provide it in a form that cannot readily be vomited. The following formula as suggested by Sauer may be used . farina or rice flour, 3 tablespoons ; skimmed milk, 9 oz , water, 12 oz , dextri-maltose, 3 tablespoons. This is boiled for one hour in a covered saucepan and should be of such a consistency that it will stick to an inverted spoon The food should be given warm and may be administered either on a spoon or a spatula, or forced with a glass rod through a Hygiea teat in which a large hole has been made , 2 to 6 tablespoons of this paste may be given six to seven times per day, depending upon the size and condition of the infant It is of the utmost importance to remember that with this type of feeding the child is receiving very little fluid and this will have to be made good with either rectal or subcutaneous salines

Good results are also claimed for feeding with skimmed lactic acid milk with the addition of dextri-maltose, 1½ oz to 1 pint Six to eight feeds should be given in the 24 hours, commencing with small feeds of about 2 oz and gradually increasing according to the child's age and condition As the vomiting decreases and the general health improves whole lactic acid milk may be gradually substituted

Drugs —In conjunction with dietetic treatment atropine should be given A solution of atropine sulphate 1 in 1000 is freshly prepared and is administered by mouth in a small quantity of water 15 minutes before each feed The initial dose is 1 minim , the patient is watched and if no toxic effects are observed the dose is gradually increased by 1 minim until flushing of the skin appears, this dose or slightly less being then continued It may be necessary to go on using it for several months Good results have been reported from the continent of alternate doses of atropine and intracutaneous injections of ¼ mg. doses of adrenalin hydrochloride, 1 in 1000

St Thomas's Hospital

UNIVERSITY COLLEGE HOSPITAL —The report for 1925 records that of the 315 available beds 305 were constantly occupied ; the in-patients numbered 5193, and there were nearly a quarter of a million attendances in the out-patient department The Dental Hospital had 12 711 patients, and the ear, nose and throat department 585 in-patients attributed to general toxic effects, is going to be repeated, it seems clear that this method may fall into disuse In view of the very real value of cholecystography in clinical medicine such an event would be regrettable The position is somewhat analogous to that which arose when salvarsan first came into general use Unreliable products were mixed with reliable ones, and much suffering was caused by inexpert administration We would suggest the following rules for the guidance of those using this method as being useful at its present stage of development (1) On account of its safety the oral route should be used as the routine method, intravenous injection being reserved for those cases where doubt remains after oral administration has been tried (2) Clinicians and pharmacists should combine in order to secure a satisfactory coating for the dye for its oral administration (3) When the intravenous route is used substances of guaranteed purity should be employed, and users should remember that this description cannot be given to all the preparations obtainable (4) Intravenous solutions must be freshly prepared, a very few hours sufficing to produce serious decomposition of these compounds (5) Extravasation during intravenous injection may lead to serious local effects, and the employment of stale compounds, impure compounds, or compounds in too high a concentration may lead to very serious general effects

If these rules are remembered the full value of this promising diagnostic innovation should be explored without danger to the public We understand that Prof Graham and his colleagues have evolved a substance more satisfactory for injection than any of those at present on the market, which will shortly be available In any case the standards of purity desirable for any of these dyes, when administered to the human subject, might well form the subject of investigation by the Pharmaceutical Society, to whom the task of the standardisation of other drugs and biological products has recently been entrusted by the Medical Research Council

---

Progress of the London Hospitals—The statistical report of the Hospital Economy Committee of King Edward's Fund for 1925 states that the 118 hospitals which come within the purview of the Fund dealt with seven million out-patient attendances The number of beds has increased by 240 to 13,700 , the average number occupied was 500 more, and there were 10,400 more in-patients The receipts were £3,029,000—a gratifying increase—and the expenditure was £2,906,000, an increase of £150,000 There has, however, been a reduction in the cost per unit, and whereas in 1920 there were 77 hospitals which failed to meet their expenditure, last year the number fell to 49 In addition to annual income, the 118 hospitals raised £691,000 for building and equipment and £167,000 for endowment, bringing the total receipts up to £3,887,000 Of the annual income only 19 per cent was derived from investments

Financial Position of St Thomas's Hospital—Sir Arthur Stanley, the treasurer, reports that the financial results of the working of the hospital in 1925 were "very disappointing," and that the future is "regarded with considerable anxiety" Expenditure exceeded income by more than £36,000, and there is a debt to the bank of nearly £98,000 Work increases out of all proportion to receipts, and if the gulf between incomings and outgoings cannot be bridged the governors "will be most reluctantly obliged to consider the expediency of reducing their work" Last year there were 11,318 in-patients, staying an average of 18 days at a cost of £11 11*s* 8*d* each The 96,110 new out-patients cost 10*s* 5*d* each

Westminster Ophthalmic Hospital—The plans for the new building in Broad-street, W C 1, which will shortly be begun, provide for an out-patients' department which will accommodate from 300 to 400 patients and beds for 30 female and 22 male in-patients, including 10 for cataract cases for each sex , there will also be a children's ward and separate wards for paying patients An entire floor will be given up to the nurses The new site is nearly three times the size of the old one

Queen Charlotte's Maternity Hospital—Last year 1906 women were delivered in the hospital, of whom 19 died, and 1842 in their own homes 2 of whom died The Antenatal Department gave 14 078 attendances to 5567 patients, and during the last 50 years 11 891 persons have been trained in midwifery and monthly nursing

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CLXXXVII

TREATMENT OF CONGENITAL HYPERTROPHIC PYLORIC STENOSIS

One of the most important factors in the treatment of congenital pyloric stenosis is early diagnosis Upon this may depend success or failure of treatment In any case in which an infant of a few weeks old, especially if a male, presents the symptom-complex of projectile vomiting, constipation, and wasting, careful examination should be made either during or immediately after a feed to ascertain if any gastric peristalsis can be observed, and to see if, by careful palpation, a pyloric tumour can be discovered Palpation of the pyloric tumour may not be an easy matter and often it is necessary to spend a considerable time over the examination Difficulty may arise from the fact that the tumour is tucked up under the liver When the disease is far advanced diagnosis is usually simple enough, but the early cases are easily missed The practitioner is often misled by the fact that a change in diet may stop the vomiting temporarily and one food after another is tried in the hope of finding the right one X ray examination after an opaque meal is valuable in establishing the diagnosis in doubtful cases, and if due care is taken no harm will result to the infant

The diagnosis having been established there are two courses open, the one surgical treatment, the other medical In deciding which course to adopt it must be remembered that delay greatly prejudices the infant's chance of recovery The practice of giving medical treatment a trial and resorting to operation only if it proves unsatisfactory is to be condemned on the grounds that the general condition of the infant will by then be less suited to withstand the shock of an operation Medical treatment is never advisable in the very acute cases or in a breast-fed baby In the former the vomiting is so persistent and the downward progress so rapid that there is no time for the patient to respond to it ; in the latter, owing to the length of time taken to effect a cure, there is a very real danger of the mother losing her milk from mental strain and anxiety In this case the baby has the additional handicap of having to adapt itself to an artificial food No case should be considered too severe for operation , often the most unlikely cases come through the best Medical treatment is best adapted to mild cases where the vomiting is slight and the general condition good, more particularly to those in which the disease has not been recognised until between the second and third month and the condition is already beginning to cure itself

To sum up, surgical treatment is to be recommended in all but the very mild cases ; but it must be remembered that the good results obtained in this country by surgical treatment have been largely due to the fact that the surgeons have been skilled in the technique of the operation The fact that the services of a specially skilled surgeon are not available may well influence the choice between surgical and medical treatment

Surgical Treatment

Pre-operative Measures—When operation has been decided upon it is usually unwise to delay it for more than two or three days This time should be devoted to the improvement of the general condition of the infant In order to remove the mucus and combat the existing gastritis gastric lavage should be started at once, and should be performed once or twice daily with a solution of sodium bicarbonate in warm water (one teaspoonful to the pint), the washing should be continued until the fluid returns clear It is important that in the day or two preceding operation the infant should receive as much nourishment as possible In as possible at the outset considerable latitude was allowed in the selection of patients for admission Now the following principles are being observed .—

(a) No case below the age of 3 years is accepted, because the nursing staff is inadequate if such are taken, and because the diagnosis is often uncertain in these cases

(b) Completely bedridden, paralysed, incontinent cases are excluded, because material improvement is in the present state of knowledge not to be expected

(c) Slight cases, presenting neither physical nor mental symptoms in any recognisable degree, admission being sought simply by way of convalescence, are refused

(d) Cases in which such mental deterioration has followed the original attack of epidemic encephalitis as to reduce the patient to the level of the mental defective are not taken, since other arrangements exist for their treatment

(e) Cases in which the diagnosis is doubtful or more than doubtful are not accepted Not all encephalitis is encephalitis lethargica or epidemica, and sporadic encephalitis, occurring in association with one or other of the exanthems, or separately has long been known

In addition to the staff of nurses a female teacher is attached to each pavilion Two masseuses give mechano-therapeutic and medico-electrical treatment to selected cases The bigger and stronger boys of the potentially "mischief-making" type are under the control of a male instructor In each pavilion of 25 children school-teaching goes on during five days a week, from 9 30 to 12, and from 1 30 to 3, lessons being interspersed with physical drill and handiwork There is ample playground and outdoor games are organised Technical medical treatment is in the hands of the resident medical officer in consultation with the visiting neurologist Systematic treatment is being planned for the Parkinsonian and other neurological cases, and a scheme of investigation in all cases

At the time of report the complete unit had only been in existence for a month or two, but much less difficulty had been encountered than expected in regard to inversion of sleep rhythm Patients who had exhibited this phenomenon in marked degree at home proved adaptable to régime, and definite improvement in normal sleep was recorded in practically every instance In the Parkinsonian group the nervous improvement shown is attributed to the effect of open air and good surroundings In many cases of behaviouristic impairment transference to the atmosphere of the unit, with its régime, discipline, regular hours, and supervision proved eminently beneficial Patient schooling is gradually resulting in a general improvement of attention on the part of these impulsive children, violent outbursts are less frequent the longer the child stays So far one case only has proved refractory, that of a girl of 8 years, who has shown deterioration over a period of some four months, and whose intellectual and emotional level is that of the mental defective.

The sequelæ of epidemic encephalitis, Dr Wilson concludes, are as diverse as the phenomena of the disease itself, hence the clinical material of the unit is, and is always likely to be, particularly heterogeneous It ranges from merely paretic or physically handicapped juveniles, of normal intellect and of good behaviour and control to so-called "moral imbeciles" (an unsatisfactory term) whose cunning and deceitfulness are linked to a certain degree of lowering of the intellectual level and who are potential young criminals All are united solely by the slender thread of a previous attack of encephalitis. It will be a matter for investigation to what extent these behaviouristic defects and apparent changes in personality are in actual fact the outcome of the brain disease, and how far, if at all, other factors than it are responsible (*To be continued*)

ST BARTHOLOMEW'S HOSPITAL.—This is one of the few voluntary hospitals which enjoys a large income from investments, and the report for 1925, which has now been issued, shows that the year's revenue from this source amounted to £120,000 out of a total of just under £185,000 There were 9191 in-patients, who stayed an average of 23 days and cost £11 13s 6d each The estimated cost of the new home for 257 sisters and nurses is £191 000, of which £44,000 has yet to be raised There were 678 students in the Medical College

VIENNA.

(FROM OUR OWN CORRESPONDENT)

Mosquitoes in Vienna.

THE unusual weather conditions of this summer have caused big floods in the neighbourhood of Vienna, especially in the valley of the Danube Vast areas of meadows and woodlands have remained under water for weeks and weeks, except for brief intervals, and in consequence Vienna is now suffering from a plague of mosquitoes Lately this has been causing some alarm, for in the old days there used to be a small focus of malaria in the city, though since 1909 the disease seems to have been stamped out There are now so many mosquitoes that the public parks and woods are full of them, and they are certainly a nuisance if not a menace Hitherto there has been no real danger of getting malaria from them, but recently true anopheles have been discovered and the public has gained some haphazard knowledge of the possible danger from reports in the newspapers The Board of Health has accordingly published a reassuring statement and is taking steps to do away with breeding places as far as they are known and are within its jurisdiction

Psycho-analysis by Laymen.

In Vienna, as elsewhere, the exponents of psycho-analysis have to face much criticism, and there is a strong feeling that only qualified medical men should be allowed to use the method Prof Freud—who by the way, has just celebrated his seventieth birthday—has amongst his pupils many who are laymen and one of them, Dr T Reik, has lately been the centre of an affair which has brought the question of the non-medical analyst into the public eye Dr Reik, who is a doctor of philosophy treated an American gentleman by psycho-analysis with the unfortunate result that the patient went from bad to worse and had a severe mental breakdown The American Consul complained to the Medical Council saying that such a quack should be stopped from continuing his evil doings and the Council informed the State Board of Health, which then held an inquiry. Dr Reik, it appears, has never claimed to be a doctor, all his patients were aware that he was not qualified, but his skill is such that Prof Freud has repeatedly handed over difficult cases to him because of his special abilities as an analyst In the controversy that has arisen Prof Freud points out that the psychic factor is not a monopoly of medical men and that it would be wrong to stop the work of so able a man as Dr Reik simply because he is not a member of the profession The authorities however, take up a much more formal attitude, they say that psycho-analysis is a strictly medical procedure, and must not be practised by a layman except under the direct supervision of a doctor This is in line with their decision about hypnotic experiments not long ago when the Supreme Board of Health acting on a report by Prof Wagner-Jauregg refused permission for hypnotic performances in public on the ground that hypnosis should only be used by qualified doctors as it may have serious consequences to mind or body if employed either as a form of treatment or for experiment.

Trichinosis in Austria

The Ministry of Health has issued a memorandum calling the attention of practitioners to the fact that in 1925 seven cases of trichinosis with three deaths were reported from Vienna and Innsbruck, and that in the first six months of this year 11 cases—with one death—were brought to the notice of the Board of Health The disease seems therefore to be on the increase and as the memorandum points out the symptoms are so vague as to escape notice unless specially looked for. The patients often complain of muscular pains, slight fever and a little general malaise, and a diagnosis of rheumatism is often

Special Articles.

METROPOLITAN ASYLUMS BOARD

SAMPLES OF THE YEAR'S WORK

A LARGE number of scientific papers are included in the medical section of the annual report for 1925–26 of the Metropolitan Asylums Board, whose general scope has already been indicated[1] A few of these papers here summarised may serve to give an idea of the wide scope and progressive character of the Board s medical work

PUERPERAL SEPSIS

Information presented to the Congress of Obstetrics held in London in 1925 showed that in cases of puerperal septicæmia confirmed by blood culture the mortality varied from 50 to 70 per cent , and that no specific treatment could be said to be of real value. The Ministry of Health, having approached the M A B with regard to the admission of cases of puerperal sepsis to certain of their hospitals, in the hope that careful investigation of these cases in bulk might lead to definite improvement in their prevention and cure, in October, 1925, 50 beds were allotted at the South-Western, the North-Western, and the Eastern Hospitals, these centres being chosen to deal with the different districts of London Mr James Wyatt, who was appointed obstetric consultant to the three hospitals, reports on the 52 cases which had passed through up to the end of February, 1926 He summarises the methods of investigation and treatment that have up to the present been adopted, adding that it is more than likely that, as our knowledge advances, they will be considerably altered, and that in any case the careful bacteriological examinations which are being carried out will increase our knowledge The general line of treatment that has been adopted is as follows —

The patient on admission is allowed to settle down in her new surroundings for some hours before any investigations are carried out Then an intra-uterine culture is taken, and if the pulse-rate has not settled after her removal to hospital to below 120 per minute a blood culture is taken The method in which the blood is dealt with before the cultures are actually taken is of great importance Local treatment is carried out very gently, as it is considered that the less the parts are disturbed the better In those cases where there is much laceration of the soft parts or the lochia are offensive vaginal lavage with liq sod chlorinatæ ℥ii in one pint of water is carried out, and later on those cases showing signs of localised peritonitis are given intra-uterine injections of glycerine, as advocated by Remington Hobbs The patients are kept in the Fowler position to aid drainage, and in some cases liq extract of ergot is given by mouth to try to stimulate the uterus General treatment consists chiefly of good nursing and suitable nourishment, and great stress is laid upon getting the patient to sleep, sedatives being used without hesitation if necessary In those cases where a positive blood culture is obtained, injection of novarsenobillon in small doses (0 3 g) is being tried, and in a few cases intravenous injection of perchloride of mercury (gr 1/16-gr 1/32) and mercurochrome 50 mg has been tried but up to date no definite conclusions can be drawn but it is to this line of treatment that special notice is being given, as it is felt that in those cases where there is infection of the blood stream it is the most likely to effect a cure.

It seems possible, says Mr Wyatt, to divide the cases of puerperal sepsis into four classes —

I An infection of the uterus which remains localised to that organ

II An infection of the uterus which spreads via the Fallopian tubes and produces either a localised or a general peritonitis

III An infection of the uterus which spreads to the pelvic cellular tissue

IV A general infection of the blood stream.

It is seldom possible at the onset of the disease to decide which class each case will fall into, but roughly in: I. The pulse is practically never raised above 120 and within two or four days the temperature falls II The temperature remains up for many days, in some cases for weeks, the pulse varies, but, unless the peritonitis is general, is again seldom above 120 There is pain over the lower abdomen, and, on bimanual examination, evidence of inflammation around the uterus, especially in the pouch of Douglas III This is usually of late onset, tenth to fourteenth day of puerperium, although there is usually evidence of the presence of some sepsis in the earlier days, which apparently subsides and then flares up again and on bimanual examination, the cellular tissue at the sides and in front of the uterus is found to be involved IV In these cases the pulse appears to be the best guide and if it remains above 130 for 24 hours it strongly suggests a general infection.

Allotting the 52 cases under these four headings, Mr Wyatt reports —

I —Thirty-one came under Class I local uterine infection All recovered In the majority of the cases the temperature and pulse settled within a few days, and in six only continued for more than seven days In 21 of the cases intra-uterine cultures were taken In 14 hæmolytic streptococci were present In seven, other organisms—non-hæmolytic streptococci, *B proteus*, diphtheroids, *B coli* The cases in which no swab was taken settled down within 24 hours of admission

II —Eleven came under Class II spread of infection to the peritoneal cavity Of these three with general peritonitis died No organisms were found in the blood, but in one in which uterine culture was taken hæmolytic streptococci were present Eight with pelvic peritonitis and salpingitis recovered In four of these hæmolytic streptococci were found in the uterus, and in four, other organisms—diphtheroids, &c One of these cases was later operated upon elsewhere and a pyosalpinx removed

III —Two with venous infection, both died One had a pulmonary embolism, one had a femoral thrombosis Hæmolytic streptococci were found in the uterine culture of both cases The patient with the femoral thrombosis also had probably a general infection, although the blood cultures were negative

IV —Seven under the heading of Class IV —viz., septicæmia In six hæmolytic streptococci in blood In one *Staphylococcus aureus* in blood Of these, four died and three recovered In all of them either novarsenobillon in doses of 0 3-0 9 g , or hydrarg perchlor gr 1/32-1/16, or mercurochrome 50 mg were given

In the septicæmic cases that recovered the infection appeared to be not severe, and Mr Wyatt suggests that the virulence of the infecting organisms varies considerably in different cases Attempts are being made to confirm this, as there is no doubt that with regard to the most prevalent organism, the hæmolytic streptococcus, this may be found in the vagina before delivery and yet perfectly normal puerperia supervene

Detailed reports by Dr R Swyer of two interesting cases of puerperal fever are appended

THE POST-ENCEPHALITIS UNIT

Dr S A Kinnier Wilson, consulting neurologist to the Board, reports on the initiation of the post-encephalitis unit opened at the Northern Hospital, Winchmore Hill, in the autumn of last year under the temporary charge of Dr Thomas Lindsay, lent from the Mental Hospitals Service The unit occupies four pavilions of 25 beds each, two being for boys and two for girls , these are now fully occupied, and there is a waiting list for admission The purpose of the unit is to observe and treat the after effects physical and mental, of children who have had an attack of lethargic or epidemic encephalitis—so called "sleepy sickness" From the outset it was decided that no clear-cut differentiation could be drawn between cases exhibiting nervous and those showing mental symptoms A number of children now in the unit show nervous disabilities with no mental or behaviouristic defects · others are perfectly well physically although their behaviour is abnormal. In order to make the number complete as quickly as possible at the outset considerable latitude was allowed in the selection of patients for admission Now the following principles are being observed —

---

[1] THE LANCET, August 21st, p 392

(*a*) No case below the age of 3 years is accepted, because the nursing staff is inadequate if such are taken, and because the diagnosis is often uncertain in these cases

(*b*) Completely bedridden, paralysed, incontinent cases are excluded, because material improvement is in the present state of knowledge not to be expected

(*c*) Slight cases, presenting neither physical nor mental symptoms in any recognisable degree, admission being sought simply by way of convalescence, are refused

(*d*) Cases in which such mental deterioration has followed the original attack of epidemic encephalitis as to reduce the patient to the level of the mental defective are not taken, since other arrangements exist for their treatment

(*e*) Cases in which the diagnosis is doubtful or more than doubtful are not accepted Not all encephalitis is encephalitis lethargica or epidemica, and sporadic encephalitis, occurring in association with one or other of the exanthems, or separately, has long been known

In addition to the staff of nurses a female teacher is attached to each pavilion Two masseuses give mechano-therapeutic and medico-electrical treatment to selected cases The bigger and stronger boys of the potentially "mischief-making" type are under the control of a male instructor In each pavilion of 25 children school-teaching goes on during five days a week, from 9 30 to 12, and from 1 30 to 3, lessons being interspersed with physical drill and handiwork There is ample playground and outdoor games are organised Technical medical treatment is in the hands of the resident medical officer in consultation with the visiting neurologist Systematic treatment is being planned for the Parkinsonian and other neurological cases, and a scheme of investigation in all cases

At the time of report the complete unit had only been in existence for a month or two, but much less difficulty had been encountered than expected in regard to inversion of sleep rhythm Patients who had exhibited this phenomenon in marked degree at home proved adaptable to régime, and definite improvement in normal sleep was recorded in practically every instance In the Parkinsonian group the nervous improvement shown is attributed to the effect of open air and good surroundings In many cases of behaviouristic impairment transference to the atmosphere of the unit, with its régime, discipline, regular hours, and supervision proved eminently beneficial Patient schooling is gradually resulting in a general improvement of attention on the part of these impulsive children, violent outbursts are less frequent the longer the child stays So far one case only has proved refractory, that of a girl of 8 years, who has shown deterioration over a period of some four months, and whose intellectual and emotional level is that of the mental defective

Mosquitoes in Vienna

THE unusual weather conditions of this summer have caused big floods in the neighbourhood of Vienna, especially in the valley of the Danube Vast areas of meadows and woodlands have remained under water for weeks and weeks, except for brief intervals, and in consequence Vienna is now suffering from a plague of mosquitoes Lately this has been causing some alarm, for in the old days there used to be a small focus of malaria in the city, though since 1909 the disease seems to have been stamped out There are now so many mosquitoes that the public parks and woods are full of them, and they are certainly a nuisance if not a menace Hitherto there has been no real danger of getting malaria from them, but recently true anopheles have been discovered and the public has gained some haphazard knowledge of the possible danger from reports in the newspapers The Board of Health has accordingly published a reassuring statement and is taking steps to do away with breeding places as far as they are known and are within its jurisdiction

Psycho-analysis by Laymen.

In Vienna, as elsewhere, the exponents of psycho-analysis have to face much criticism, and there is a strong feeling that only qualified medical men should be allowed to use the method Prof Freud—who, by the way, has just celebrated his seventieth birthday—has amongst his pupils many who are laymen and one of them, Dr T Reik, has lately been the centre of an affair which has brought the question of the non-medical analyst into the public eye Dr Reik, who is a doctor of philosophy, treated an American gentleman by psycho-analysis with the unfortunate result that the patient went from bad to worse and had a severe mental breakdown The American Consul complained to the Medical Council, saying that such a quack should be stopped from continuing his evil doings and the Council informed the State Board of Health, which then held an inquiry. Dr Reik, it appears, has never claimed to be a doctor, all his patients were aware that he was not qualified, but his skill is such that Prof Freud has repeatedly handed over difficult cases to him because of his special abilities as an analyst In the controversy that has arisen Prof Freud points out that the psychic factor is not a monopoly of medical men and that it would be wrong to stop the work of so able a man as Dr Reik simply because he is not a member of the profession The authorities, however take up a much more formal attitude, they say that psycho-analysis is a strictly medical procedure, and must not be practised by a layman except under the direct supervision of a doctor This is in line with their decision about hypnotic experiments not long ago, when the Supreme Board of Health, acting on a report by Prof Wagner-Jauregg refused permission for hypnotic performances in public on the ground that hypnosis should only be used by qualified doctors as it may have serious consequences to mind or body if employed either as a form of treatment or for experiment.

Trichinosis in Austria

The Ministry of Health has issued a memorandum calling the attention of practitioners to the fact that in 1925 seven cases of trichinosis with three deaths were reported from Vienna and Innsbruck, and that in the first six months of this year 11 cases—with one death—were brought to the notice of the Board of Health The disease seems, therefore, to be on the increase, and as the memorandum points out the symptoms are so vague as to escape notice unless specially looked for The patients often complain of muscular pains, slight fever and a little general malaise, and a diagnosis of rheumatism is often

Special Articles.

METROPOLITAN ASYLUMS BOARD.

SAMPLES OF THE YEAR'S WORK.

A LARGE number of scientific papers are included in the medical section of the annual report for 1925–26 of the Metropolitan Asylums Board, whose general scope has already been indicated[1] A few of these papers here summarised may serve to give an idea of the wide scope and progressive character of the Board s medical work

Puerperal Sepsis.

Information presented to the Congress of Obstetrics held in London in 1925 showed that in cases of puerperal septicæmia confirmed by blood culture the mortality varied from 50 to 70 per cent, and that no specific treatment could be said to be of real value. The Ministry of Health, having approached the M A B with regard to the admission of cases of puerperal sepsis to certain of their hospitals, in the hope that careful investigation of these cases in bulk might lead to definite improvement in their prevention and cure, in October, 1925, 50 beds were allotted at the South-Western, the North-Western, and the Eastern Hospitals, these centres being chosen to deal with the different districts of London Mr James Wyatt, who was appointed obstetric consultant to the three hospitals, reports on the 52 cases which had passed through up to the end of February, 1926 He summarises the methods of investigation and treatment that have up to the present been adopted, adding that it is more than likely that, as our knowledge advances, they will be considerably altered, and that in any case the careful bacteriological examinations which are being carried out will increase our knowledge The general line of treatment that has been adopted is as follows —

The patient on admission is allowed to settle down in her new surroundings for some hours before any investigations are carried out Then an intra-uterine culture is taken, and if the pulse-rate has not settled after her removal to hospital to below 120 per minute a blood culture is taken The method in which the blood is dealt with before the cultures are actually taken is of great importance Local treatment is carried out very gently, as it is considered that the less the parts are disturbed the better In those cases where there is much laceration of the soft parts or the lochia are offensive vaginal lavage with liq sod chlorinatæ ℥ii in one pint of water is carried out, and later on those cases showing signs of localised peritonitis are given intra-uterine injections of glycerine, as advocated by Remington Hobbs The patients are kept in the Fowler position to aid drainage, and in some cases liq extract of ergot is given by mouth to try to stimulate the uterus General treatment consists chiefly of good nursing and suitable nourishment, and great stress is laid upon getting the patient to sleep, sedatives being used without hesitation if necessary In those cases where a positive blood culture is obtained, injection of novarsenobillon in small doses (0 3 g) is being tried, and in a few cases intravenous injection of perchloride of mercury (gr 1/16–gr 1/32) and mercurochrome 50 mg has been tried, but up to date no definite conclusions can be drawn, but it is to this line of treatment that special notice is being given, as it is felt that in those cases where there is infection of the blood stream it is the most likely to effect a cure.

It seems possible, says Mr Wyatt, to divide the cases of puerperal sepsis into four classes —

I An infection of the uterus which remains localised to that organ

II An infection of the uterus which spreads via the Fallopian tubes and produces either a localised or a general peritonitis

III An infection of the uterus which spreads to the pelvic cellular tissue

IV A general infection of the blood stream

It is seldom possible at the onset of the disease to decide which class each case will fall into, but roughly in. I The pulse is practically never raised above 120 and within two or four days the temperature fall II The temperature remains up for many days in some cases for weeks, the pulse varies, but, unless the peritonitis is general, is again seldom above 120 There is pain over the lower abdomen, and, on bimanual examination, evidence of inflammation around the uterus, especially in the pouch of Douglas III Th is usually of late onset, tenth to fourteenth day of puerperium, although there is usually evidence of the presence of some sepsis in the earlier days, which apparently subsides and then flares up again and on bimanual examination, the cellular tissue at the sides and in front of the uterus is found to be involved IV In these cases the pulse appears to be the best guide and if it remains above 130 for 24 hours it strongly suggests a general infection

Allotting the 52 cases under these four headings, Mr Wyatt reports —

I —Thirty-one came under Class I local uterine infection. All recovered In the majority of the cases the temperature and pulse settled within a few days, and in six only continued for more than seven days In 21 of the cases intra-uterine cultures were taken In 14 hæmolytic streptococci were present In seven, other organisms—non-hæmolytic streptococci, *B proteus*, diphtheroids *B coli* The cases in which no swab was taken settled down within 24 hours of admission

II —Eleven came under Class II spread of infection to the peritoneal cavity Of these three with general peritonitis died No organisms were found in the blood, but in one in which uterine culture was taken hæmolytic streptococci were present Eight with pelvic peritonitis and salpingitis recovered In four of these hæmolytic streptococci were found in the uterus, and in four, other organisms—diphtheroids, &c One of these cases was later operated upon elsewhere and a pyosalpinx removed

III —Two with venous infection, both died One had a femoral thrombosis One had a pulmonary embolism. Hæmolytic streptococci were found in the uterine culture of both cases The patient with the femoral thrombosis also had probably a general infection, although the blood cultures were negative

IV —Seven under the heading of Class IV—viz., septicæmia In six hæmolytic streptococci in blood In one *Staphylococcus aureus* in blood Of these, four died and three recovered In all of them either novarsenobillon in doses of 0 3-0 9 g, or hydrarg perchlor gr 1/32 1/10, or mercurochrome 50 mg were given

In the septicæmic cases that recovered the infection appeared to be not severe, and Mr Wyatt suggests that the virulence of the infecting organisms varies considerably in different cases Attempts are being made to confirm this, as there is no doubt that with regard to the most prevalent organism, the hæmolytic streptococcus, this may be found in the vagina before delivery and yet perfectly normal puerperia supervene

Detailed reports by Dr R Swyer of two interesting cases of puerperal fever are appended

The Post-Encephalitis Unit

Dr S A Kinnier Wilson, consulting neurologist to the Board, reports on the initiation of the post-encephalitis unit opened at the Northern Hospital, Winchmore Hill, in the autumn of last year under the temporary charge of Dr Thomas Lindsay, lent from the Mental Hospitals Service The unit occupies four pavilions of 25 beds each, two being for boys and two for girls, these are now fully occupied, and there is a waiting list for admission The purpose of the unit is to observe and treat the after effects, physical and mental, of children who have had an attack of lethargic or epidemic encephalitis—so called "sleepy sickness" From the outset it was decided that no clear-cut differentiation could be drawn between cases exhibiting nervous and those showing mental symptoms A number of children now in the unit show nervous disabilities with no mental or behaviouristic defects others are perfectly well physically although their behaviour is abnormal. In order to make the numbers complete as quickly

[1] The Lancet, August 21st, p 392

In consequence of a report by the Minister of Agriculture, the price of bread in Paris will be lowered by several sous per kilo An inexplicable rise in the price of milk has been proved unlawful. and the dairy associations responsible for the advance will be prosecuted

Dr Ménard, radiological chief at the Hôpital Cochin, died on August 7th after a long struggle against the effects of X rays His right hand had to be amputated in 1908, his face was attacked in 1917. and his left eye removed in 1925. Notwithstanding these grave complications, Menard continued to work valiantly to the last. Gaston Danne director of the radiological laboratory at Gif, who has made important inventions of radium tubes, electrometers, electroscopes, and other apparatus. has also joined the ranks of those whose devotion to radiology has rewarded them so sadly. Both these victims to their duty have been cited to the Order of the Nation.

Madame Curie, who left France about the middle of July, is delivering a series of lectures in Brazil on radium

The fiftieth anniversary of the Societe de Medecine Publique will be celebrated during the latter half of October, 1927, in connexion with the Fourteenth French Congress on Hygiene Prof. T. Madsen. of Copenhagen, will deliver the principal address. Particulars may be had from Dr. Dujarric de la Riviere, Institut Pasteur, 25 rue Dutot, Paris

The Office National des Recherches et Inventions is opening a competition for devices to remove from the air solid particles derived from smoke. dust, and gas combustion Inventors who propose to compete should enter their names before Oct. 1st. Satisfactory tests are required, and should be completed by Jan. 1st, 1927; the official tests will not begin before July 1st, 1927.

A post-graduate course in Gastro-intestinal Diseases will be held at the Hotel Dieu, Paris, from Sept 13th to 27th For details apply to the Secrétariat, Faculte de Medecine, 12 rue de l'École de Medecine

IRELAND

(From our own Correspondent)

Census of the Irish Free State

The preliminary report on the Census of the Irish Free State, which was taken on the night of April 18th–19th last, has recently been published, and will disappoint those who hoped to see some check to the depopulation of Ireland which has now been progressive since 1841 Two facts emerge as characteristic of the movement of population in Ireland as a whole—namely, the decrease of population, and the increase of the larger towns Since 1911, the last census year, the population of Ireland has decreased from 4,390 219 to 4 229,124—a decrease of 161,095 or 3 7 per cent This decrease is the balance of a decrease of 5 3 per cent in the area of the Irish Free State and an increase of 0 5 per cent in the area of Northern Ireland The increase in Northern Ireland is symbolic of the increase in the population of the larger towns coincident with a decrease in the rural areas The density of population in the Free State is less than half that in Northern Ireland—112 and 240 persons to the square mile respectively The density in England and Wales is 649 and in Scotland 161. No less than 63 2 per cent of the population of the Free State live in "country districts," that is to say, outside towns or villages of 200 or more inhabitants The progressive depopulation of the country districts as compared with the growth of Dublin and its suburbs is shown by the following figures Since 1841 the "country districts" (as defined above) have lost 64 4 per cent of their population villages of from 200 to 500 inhabitants have lost 49 1 per cent; towns of 500 to 2000, 13 per cent; of 2000 to 5000 33 3 per cent.; of 5000 to 10,000, 25 per cent.; towns over 10 000 (other than the metropolitan area), 13 per cent.; while Dublin and the four adjoining suburban districts have gained 47 per cent. The emigration rate, which had been decreasing gradually from 1881 to 1911, now shows a slight rise. being 8 8 per 1000 persons per year as against 8 2 for the years 1901–11. The birth-rate and the death-rate both continue to decline. The birth-rate is now 21 1 per 1000 persons. and the death-rate 16 per 1000.

In a table of 24 European countries Ireland shows by far the highest proportion of its natives living overseas. Thus the Irish living overseas bear to those at home the proportion of 30 5 per cent Nearest to this comes Norway with 14 8 per cent, and then Scotland with 14·1 per cent. These percentages do not take account of intro-European migration. Since 1871 there has been a steady decline in the ratio of females to males in Ireland, the ratio at present being 999 to 1000. The figure is lowest in the most rural areas, in the three counties of Ulster which are in the Free State being as low as 939. and in Connaught 944. On the other hand, in Northern Ireland there are 1066 females to each 1000 males

Centenary of the Coombe Hospital.

The Coombe Maternity Hospital, Dublin, was founded in 1826, and therefore is now completing its hundredth year. An interesting celebration has been arranged and will be held from Sept. 14th to 17th. Several famous obstetricians and gynæcologists have been invited to visit Dublin, and the forenoon of each day will be devoted to the discussion of some subject of obstetric or gynæcological interest. Sir William J. Smyly, a past Master of the Rotunda Hospital, will preside at the meetings. A discussion on Obstetrical Teaching in Sweden will be opened by Prof Essen Möller, of Lund, and one on Eclampsia by Prof. Hinselmann, of Altona. A large number of other papers will be read, and among those taking part will be Prof Couvelaire and Prof Faure (Paris), Prof Munro Kerr (Glasgow), Mr. Eardley Holland (London), Prof. Werner (Vienna), Mr. A Donald (Manchester), Prof. R W. Johnstone (Edinburgh), and Prof B Whitehouse (Birmingham) The afternoons and evenings will be occupied with various social functions, the opening ceremony being an evening reception in the Royal College of Surgeons, given by the governors of the Coombe Hospital, and the closing function a garden party at the Royal Zoological Society

WOMEN'S MEDICAL SERVICE FOR INDIA

Among careers open to medical women abroad the Women's Medical Service for India deserves honourable mention This service is open to fully qualified medical women of British or Indian nationality and with the present amount of Government subsidy the number of medical officers is limited to 44 Medical women proceeding to India to join the Women's Medical Service receive a sufficient sum for a first-class passage to India On landing they are posted to one of the larger women's hospitals to gain Indian experience and to learn the language During this period (from six months to two years) private practice is not allowed For a further period they are appointed to act temporarily for medical women on furlough, during which time private practice is allowed They are then definitely appointed to the charge of hospitals Private practice is always allowed after the first two years, provided it does not interfere with official duties. The only exception is in administrative or educational posts, when an allowance in lieu of practice is given The amount obtained from practice varies according to the station but in most cases it forms a fair addition to the salary, varying from £150 to £1000 a year.

Excellent opportunities for surgery—especially gynæcological—are found in the Women's Medical Service To those who are not keen surgeons oppormade Even when nodules are discovered in the muscles their cause may be mistaken The most reliable method of diagnosis—microscopical examination of an excised nodule—is hardly feasible in patients who are only slightly affected Examination of the blood for eosinophilia is very useful, it is easily done, the patients do not mind it, and it should never be omitted when there is any suspicion of trichinosis Probably the people of the countryside are often affected without knowing it, for smoked (not boiled) pork is a very common article of diet in rural districts, especially in the woodlands The Ministry has made arrangements for free pathological examination of any specimens sent up to Vienna with a tentative diagnosis of trichinosis

A New Surgical Disinfectant

At a recent meeting of the Surgical Society of Vienna Prof Paul Albrecht reported on the use of a new disinfectant for dressing wounds During the war the chief disinfectant in use amongst the Allies was chlorine, whilst iodine was preferred by surgeons of the Central Powers In 1921 Prof Ulzer prepared a solution containing both these germicides and this he has now improved by the addition of fluoric acid This aqueous solution is in use at the surgical station of Prof Albrecht, and has been found very satisfactory After a phlegmonous abscess is opened the wound is gently packed with gauze soaked in the solution, and a wet dressing applied This is repeated every three hours and the decursus morbi is very good It has also been used in surgical tuberculosis and in treating accidental wounds, mostly dirty, inflammation rapidly subsided and injuries healed quickly For the last year or so, furthermore, this "halogen solution" has been employed as an adjuvant in so-called aseptic operations, in order to destroy or make innocuous the white staphylococcus Albrecht has used it in 14 strumectomies, 19 laparotomies, and 14 operations for cancer of the breast He claims that it does not injure the tissues even when in contact with them for a long time The tuberculous glands were treated without drainage, the wounds being closed at once after swabbing them out well with the solution In only three of the cases of mammary cancer was drainage employed, and hæmorrhage or serous exudate under the skin was always sterile, most remarkable was the rapid apposition of the skin laps to the walls of the thorax Formation of very tough scar tissue is the rule after the use of the halogen solution, and it seems as though the solution definitely promotes the formation of connective tissue The theoretical explanation of this process is as yet unknown

PARIS

(FROM OUR OWN CORRESPONDENTS)

Arterial Hypertension

Dr Mattei and Dr Dias-Cavaroni, of Marseilles, have been studying the effects of various drugs upon arterial hypertension, and recently gave in the *Presse Médicale* an account of their observations on sodium nitrite, nitroglycerine benzyl benzoate, chloral, tincture of garlic, and mistletoe Sodium nitrite, they say, is generally useless, and may also be dangerous, the action of nitroglycerine is transitory and uncertain, and these two substances have the unfavourable effect of increasing the value of the oscillometric index without sensibly lowering arterial tension Benzyl benzoate and tincture of garlic have a very feeble and inconstant action on arterial hypertension, but mistletoe and chloral are found to be fairly satisfactory and regular in their action An aqueous extract of mistletoe, given by intramuscular injection, lowers the systolic pressure and also acts, rather later and with less regularity, on the diastolic pressure Chloral given by the mouth for several days causes definite lowering of systolic pressure with variations of the diastolic which, although appreciable, are slight. Even in favourable cases the action of mistletoe and chloral does not last more than about 10 days, and the best of these remedies appear to have a transient effect on hypertension, acting especially by reducing the raised systolic pressure which is often a sign of compensatory hypersystole Their effect is not wholly satisfactory unless at the same time a parallel reduction of the diastolic is caused by rest purgatives, diuretics, cardiac tonics, and suitable régime In practice it may be said that there are no such things as hypotensor remedies, though there is a treatment which reduces tension

Marriage Problems

The question of examination before marriage came up at a meeting of the International Eugenics Committee which met at Paris in July under the presidency of Major Leonard Darwin Dr George Schreiber, of Paris, explained the advantages of the Scandinavian system, which demands from candidates for marriage a medical certificate given by a doctor chosen by the interested parties, and other speakers described the customs in vogue in the United States Holland, and Belgium At the same conference Vignes and Apert, of Paris, discussed consanguinity in marriage They pointed out that in unions between first cousins there are only three pairs of grandparents instead of four, and that the pair which is common to the two cousins who wish to marry is the pair which it is most important to study from the point of view of heredity Prof Buchanan Smith, of Edinburgh, described his own observations on in-breeding amongst animals An important discussion followed these papers, the general impression seeming to be that consanguinity leads to fixation of good characteristics just as much as bad, and that it is important above all to search for hereditary familial diseases before giving sanction to marriage between relatives

Nickel and Cobalt in Diabetes

Two important communications have recently been made to the Académie des Sciences on the use of nickel and cobalt in the treatment of diabetes Subcutaneous injection, or even oral administration, of very small amounts of nickel and cobalt have led to benefit in some cases of diabetes, and sometimes there has even been complete suppression of sugar in the urine with disappearance of polyuria and thirst increased tolerance for glucose, and sometimes though not always, lowering of blood-sugar On the other hand, in certain conditions, such as infantile diabetes and diabetes associated with tuberculosis there seems to be no effect In six cases of diabetes with tuberculosis after several injections the glycosuria became worse, the blood-sugar was raised, and excretion of acetone bodies increased, the treatment had to be stopped With reservations, however, these remedies seem to have real usefulness

Inflammability of Artificial Silk

The manufacture of artificial silk is steadily increasing, but it has its dangers; the kind most common on the market has not been denitrified, and is explosive as well as inflammable A single spark is enough to cause a conflagration Two young people have recently been burnt through wearing mufflers made of silk which had not been denitrified When damages were asked for the Courts acquitted the manufacturers on the ground that the accidents had not been foreseen

Immunisation of the Newborn against Tetanus

Prof Roux has communicated to the Académie des Sciences the results of tests made by Nattan-Larrier, Ramon, and Grasset These tests show that newborn infants may be immunised against tetanus by means of the anatoxin, analogous to diphtheritic anatoxin worked out by Ramon Immunity may also be conferred before birth by giving injections of anatoxin to the prospective mother

In consequence of a report by the Minister of Agriculture, the price of bread in Paris will be lowered by several sous per kilo. An inexplicable rise in the price of milk has been proved unlawful, and the dairy associations responsible for the advance will be prosecuted.

Dr. Menard, radiological chief at the Hôpital Cochin, died on August 7th after a long struggle against the effects of X rays. His right hand had to be amputated in 1908, his face was attacked in 1917, and his left eye removed in 1925. Notwithstanding these grave complications, Menard continued to work valiantly to the last. Gaston Danne director of the radiological laboratory at Gif, who has made important inventions of radium tubes, electrometers, electroscopes and other apparatus has also joined the ranks of those whose devotion to radiology has rewarded them so sadly. Both these victims to their duty have been cited to the Order of the Nation.

Madame Curie, who left France about the middle of July, is delivering a series of lectures in Brazil on radium.

The fiftieth anniversary of the Societé de Médecine Publique will be celebrated during the latter half of October, 1927, in connexion with the Fourteenth French Congress on Hygiene. Prof. T. Madsen, of Copenhagen, will deliver the principal address. Particulars may be had from Dr. Dujarric de la Riviere, Institut Pasteur, 25 rue Dutot, Paris.

Inventors who propose to compete should enter their names before Oct. 1st. Satisfactory tests are required, and should be completed by Jan. 1st, 1927; the official tests will not begin before July 1st, 1927.

A post-graduate course in Gastro-intestinal Diseases will be held at the Hotel Dieu, Paris, from Sept. 13th to 27th. For details apply to the Secretariat, Faculte de Medecine, 12 rue de l'École de Médecine.

IRELAND

(FROM OUR OWN CORRESPONDENT.)

Census of the Irish Free State

THE preliminary report on the Census of the Irish Free State, which was taken on the night of April 18th–19th last has recently been published, and will disappoint those who hoped to see some check to the depopulation of Ireland which has now been progressive since 1841. Two facts emerge as characteristic of the movement of population in Ireland as a whole—namely, the decrease of population, and the increase of the larger towns. Since 1911, the last census year, the population of Ireland has decreased from 4,390,219 to 4,229,124—a decrease of 161,095 or 3·7 per cent. This decrease is the balance of a decrease of 5·3 per cent. in the area of the Irish Free State and an increase of 0·5 per cent. in the area of Northern Ireland. The increase in Northern Ireland is symbolic of the increase in the population of the larger towns coincident with a decrease in the rural areas. The density of population in the Free State is less than half that in Northern Ireland—112 and 240 persons to the square mile respectively. The density in England and Wales is 649 and in Scotland 161. No less than 63·2 per cent. of the population of the Free State live in "country districts," that is to say, outside towns or villages of 200 or more inhabitants. The progressive depopulation of the country districts as compared with the growth of Dublin and its suburbs is shown by the following figures. Since 1841 the "country districts" (as defined above) have lost 64·1 per cent. of their population; villages of from 200 to 500 inhabitants have lost 49·1 per cent.; towns of 500 to 2000, 43 per cent.; of 2000 to 5000, 33·3 per cent.; of 5000 to 10,000, 25 per cent.; towns over 10,000 (other than the metropolitan area), 13 per cent.; while Dublin and the four adjoining suburban districts have gained 47 per cent. The emigration rate, which had been decreasing gradually from 1881 to 1911, now shows a slight rise, being 8·8 per 1000 persons per year as against 8·2 for the years 1901–11. The birth-rate and the death-rate both continue to decline. The birth-rate is now 21·1 per 1000 persons and the death-rate 16 per 1000.

In a table of 24 European countries Ireland shows by far the highest proportion of its natives living overseas. Thus the Irish living overseas bear to those at home the proportion of 30·5 per cent. Nearest to this comes Norway with 14·8 per cent., and then Scotland with 14·1 per cent. These percentages do not take account of intro-European migration. Since 1871 there has been a steady decline in the ratio of females to males in Ireland, the ratio at present being 999 to 1000. The figure is lowest in the most rural areas, in the three counties of Ulster which are in the Free State being as low as 939, and in Connaught 944. On the other hand, in Northern Ireland there are 1066 females to each 1000 males.

Centenary of the Coombe Hospital

The Coombe Maternity Hospital, Dublin, was founded in 1826, and therefore is now completing its hundredth year. An interesting celebration has been arranged and will be held from Sept. 14th to 17th. Several famous obstetricians and gynæcologists have been invited to visit Dublin, and the forenoon of each day will be devoted to the discussion of some subject of obstetric or gynæcological interest. Sir William J. Smyly, a past Master of the Rotunda Hospital, will preside at the meetings. A discussion on Obstetrical Teaching in Sweden will be opened by Prof. Essen Möller, of Lund, and one on Eclampsia by Prof. Hinselmann, of Altona. A large number of other papers will be read, and among those taking part will be Prof. Couvelaire and Prof. Faure (Paris), Prof. Munro Kerr (Glasgow), Mr. Eardley Holland (London), Prof. Werner (Vienna), Mr. A. Donald (Manchester), Prof. R. W. Johnstone (Edinburgh), and Prof. B. Whitehouse (Birmingham). The afternoons and evenings will be occupied with various social functions, the opening ceremony being an evening reception in the Royal College of Surgeons, given by the governors of the Coombe Hospital, and the closing function a garden party at the Royal Zoological Society.

WOMEN'S MEDICAL SERVICE FOR INDIA

AMONG careers open to medical women abroad the Women's Medical Service for India deserves honourable mention. This service is open to fully qualified medical women of British or Indian nationality, and with the present amount of Government subsidy the number of medical officers is limited to 44. Medical women proceeding to India to join the Women's Medical Service receive a sufficient sum for a first-class passage to India. On landing they are posted to one of the larger women's hospitals to gain Indian experience and to learn the language. During this period (from six months to two years) private practice is not allowed. For a further period they are appointed to act temporarily for medical women on furlough, during which time private practice is allowed. They are then definitely appointed to the charge of hospitals. Private practice is always allowed after the first two years, provided it does not interfere with official duties. The only exception is in administrative or educational posts, when an allowance in lieu of practice is given. The amount obtained from practice varies according to the station, but in most cases it forms a fair addition to the salary, varying from £150 to £1000 a year.

Excellent opportunities for surgery—especially gynæcological—are found in the Women's Medical Service. To those who are not keen surgeons oppormade Even when nodules are discovered in the muscles their cause may be mistaken The most reliable method of diagnosis—microscopical examination of an excised nodule—is hardly feasible in patients who are only slightly affected Examination of the blood for eosinophilia is very useful, it is easily done, the patients do not mind it, and it should never be omitted when there is any suspicion of trichinosis Probably the people of the countryside are often affected without knowing it, for smoked (not boiled) pork is a very common article of diet in rural districts, especially in the woodlands The Ministry has made arrangements for free pathological examination of any specimens sent up to Vienna with a tentative diagnosis of trichinosis

A New Surgical Disinfectant

At a recent meeting of the Surgical Society of Vienna Prof Paul Albrecht reported on the use of a new disinfectant for dressing wounds During the war the chief disinfectant in use amongst the Allies was chlorine, whilst iodine was preferred by surgeons of the Central Powers In 1921 Prof Ulzer prepared a solution containing both these germicides and this he has now improved by the addition of fluoric acid This aqueous solution is in use at the surgical station of Prof Albrecht, and has been found very satisfactory After a phlegmonous abscess is opened the wound is gently packed with gauze soaked in the solution, and a wet dressing applied This is repeated every three hours, and the decursus morbi is very good It has also been used in surgical tuberculosis and in treating accidental wounds, mostly dirty, inflammation rapidly subsided and injuries healed quickly For the last year or so, furthermore, this "halogen solution" has been employed as an adjuvant in so-called aseptic operations, in order to destroy or make innocuous the white staphylococcus Albrecht has used it in 14 strumectomies, 19 laparotomies, and 14 operations for cancer of the breast He claims that it does not injure the tissues even when in contact with them for a long time The tuberculous glands were treated without drainage, the wounds being closed at once after swabbing them out well with the solution In only three of the cases of mammary cancer was drainage employed, and hæmorrhage or serous exudate under the skin was always sterile, most remarkable was the rapid apposition of the skin laps to the walls of the thorax Formation of very tough scar tissue is the rule after the use of the halogen solution, and it seems as though the solution definitely promotes the formation of connective tissue The theoretical explanation of this process is as yet unknown

(FROM OUR OWN CORRESPONDENTS)

Arterial Hypertension

Dr Mattei and Dr Dias-Cavaroni, of Marseilles, have been studying the effects of various drugs upon arterial hypertension, and recently gave in the *Presse Medicale* an account of their observations on sodium nitrite, nitroglycerine benzyl benzoate, chloral, tincture of garlic, and mistletoe Sodium nitrite, they say, is generally useless, and may also be dangerous ; the action of nitroglycerine is transitory and uncertain, and these two substances have the unfavourable effect of increasing the value of the oscillometric index without sensibly lowering arterial tension Benzyl benzoate and tincture of garlic have a very feeble and inconstant action on arterial hypertension, but mistletoe and chloral are found to be fairly satisfactory and regular in their action An aqueous extract of mistletoe, given by intramuscular injection, lowers the systolic pressure and also acts, rather later and with less regularity, on the diastolic pressure Chloral given by the mouth for several days causes definite lowering of systolic pressure with variations of the diastolic which, although appreciable, are slight Even in favourable cases the action of mistletoe and chloral does not last more than about 10 days, and the best of these remedies appear to have a transient effect on hypertension, acting especially by reducing the raised systolic pressure which is often a sign of compensatory hypersystole Their effect is not wholly satisfactory unless at the same time a parallel reduction of the diastolic is caused by rest purgatives, diuretics, cardiac tonics, and suitable régime In practice it may be said that there are no such things as hypotensor remedies, though there is a treatment which reduces tension

Marriage Problems

The question of examination before marriage came up at a meeting of the International Eugenics Committee which met at Paris in July under the presidency of Major Leonard Darwin. Dr George Schreiber, of Paris, explained the advantages of the Scandinavian system, which demands from candidates for marriage a medical certificate given by a doctor chosen by the interested parties, and other speakers described the customs in vogue in the United States Holland, and Belgium At the same conference Vignes and Apert, of Paris, discussed consanguinity in marriage They pointed out that in unions between first cousins there are only three pairs of grandparents instead of four, and that the pair which is common to the two cousins who wish to marry is the pair which it is most important to study from the point of view of heredity Prof Buchanan Smith of Edinburgh, described his own observations on in-breeding amongst animals An important discussion followed these papers, the general impression seeming to be that consanguinity leads to fixation of good characteristics just as much as bad, and that it is important above all to search for hereditary familial diseases before giving sanction to marriage between relatives

Nickel and Cobalt in Diabetes

Two important communications have recently been made to the Académie des Sciences on the use of nickel and cobalt in the treatment of diabetes Subcutaneous injection, or even oral administration, of very small amounts of nickel and cobalt have led to benefit in some cases of diabetes, and sometimes there has even been complete suppression of sugar in the urine with disappearance of polyuria and thirst, increased tolerance for glucose, and sometimes though not always, lowering of blood-sugar On the other hand, in certain conditions, such as infantile diabetes and diabetes associated with tuberculosis there seems to be no effect In six cases of diabetes with tuberculosis after several injections the glycosuria became worse, the blood-sugar was raised, and excretion of acetone bodies increased · the treatment had to be stopped With reservations, however, these remedies seem to have real usefulness

Inflammability of Artificial Silk

The manufacture of artificial silk is steadily increasing, but it has its dangers; the kind most common on the market has not been denitrified, and is explosive as well as inflammable A single spark is enough to cause a conflagration Two young people have recently been burnt through wearing mufflers made of silk which had not been denitrified When damages were asked for the Courts acquitted the manufacturers on the ground that the accidents had not been foreseen

Immunisation of the Newborn against Tetanus

Prof Roux has communicated to the Académie des Sciences the results of tests made by Nattan-Larrier, Ramon, and Grasset These tests show that newborn infants may be immunised against tetanus by means of the anatoxin, analogous to diphtheritic anatoxin worked out by Ramon Immunity may also be conferred before birth by giving injections of anatoxin to the prospective mother

Public Health Services.

INCAPACITY FOR WORK IN AN INDUSTRIAL CRISIS

THE growing distress among all classes of the working community in the coal-fields has given rise to some difficult problems in the assignment of relief. A few weeks ago the Ministry of Health issued a memorandum to guide insurance practitioners in interpreting the term "incapable of work," on which health benefit depends The fact of an insured person being unable on account of his health to follow his ordinary occupation is not in itself sufficient to render him "incapable of work" within the meaning of the Acts. yet he would properly be so regarded if he has early prospect of resuming his former work This fairly simple proposition becomes vastly complicated when as now. opportunity to resume former work is indefinitely delayed · according to the Ministry situations may then arise in which an insured person should not be certified as "incapable of work" unless in the doctor's opinion, he is physically unable to perform any other suitable kind of remunerative work. Much turns on this fine distinction, for boards of guardians are entitled to refuse payment of out-relief to single men concerned in the coal stoppage unless they are so reduced by privation as to be physically incapable of work. In a Northumbrian area where the guardians of the poor are themselves in financial straits, three of the relieving officers stated that they could only bring themselves within the limits of the law in the relief of single men by asking them to produce medical certificates proving physical inability to work through destitution" In this case the guardians seem to have shifted their responsibility upon the relieving officers who in their turn attempted to pass on the onus of decision to the insurance practitioners A later report states that for thus delegating their responsibility the relieving officers were suspended—leaving unsolved the problem presented for solution It must be admitted that the claim of insured persons to sickness benefit or relief based upon certain Acts of Parliament is interpreted by different authorities in different ways The duty of turning down an application for relief is essentially unpopular, with the natural result that the task is relegated whenever possible to the medical man In the absence of prescribed criteria every practitioner has to set his own standard of fitness for the healthy labourer. his judgment being tinged to a greater or smaller extent by humanity Obviously the onus of decision must not be laid on professional persons. A certificate of disability given by a practitioner conscientiously after due examination embodies no more than his considered opinion on the medical evidence and this must be taken in conjunction with all the circumstances of the case on which his opinion is apposite The professional man should be assessor. not arbiter Physical fitness is notoriously difficult to define The factors are numerous and varied and the standard is at best a rough average for fit men vary widely in physique and endurance The base-line must also be adjusted for the particular occupation The miner requires more than an average physique for his arduous work, and his physique is quickly affected by restricted diet If the sole responsibility for decision is to be put on the insurance practitioner provision should at least be made for special investigation such as determination of the applicant's basal metabolism The ergometer is already used in many pits to determine the fitness of men for work at the coal face in order to safeguard the employer It would be logical to adopt similar means in the interest of the men to determine their [illegible] to seek benefit or relief

PORT SANITARY AUTHORITIES.

Dr. W. Allen Daley reports for the first time in 1925 to the *Hull and Goole Port Sanitary Authority*. which supervises 235 acres of docks visited during the year by 9083 vessels A bacteriological laboratory has now been fitted up for the assistant medical officer to examine water from ships and rats suspected of plague If a ship reports sickness or comes from an infected port. she is boarded by the medical officer as she enters dock: infectious cases are then removed to the City Hospital Hull or to the Isolation Hospital Goole, the shipmaster guaranteeing a payment of 7*s* 6*d* per day. One ship that arrived had lost a man from plague two months before at Lagos: the ship had been fumigated then and there. and at Hull 164 rats were trapped. of which 52 were examined. but none was found infected and no fresh human case appeared Another ship reported on arrival a death from yellow fever three weeks earlier. also at Lagos: she was fumigated (no rats were killed) and no other case developed. From the same ship seven cases of malaria. one of them the ship's surgeon were removed to the City Hospital. all being discharged in ten days. Two cases of typhoid were removed from a ship from the West Indies, both recovered. Another ship mentioned had sent seven cases to hospital abroad: so typhoid is still a menace at sea Seven cases of pulmonary tuberculosis were sent to hospitals two being passengers Of the cases of illness reported on arrival, one-third (45) were cases of venereal disease. 16 were malarial. and 10 were acute bronchitis The disinfecting station has a shelter attached in which crews can be accommodated during fumigation of their ships Rats trapped in ships numbered 5286 5239 of them black. only 47 brown an average of 25 per ship; rats killed in the fumigation of ships averaged seven but most fumigations were blank. The total of rats destroyed on ships and about the port was 12 740 of the 698 examined none was plague-infected. There are venereal disease clinics at Hull Royal Infirmary and at Bartholomew Hospital Goole and the place and hours of the clinics are notified to shipmasters and patients in nine-language leaflets Samples of drinking water were taken from 28 ships and seven showed colon bacillus, those vessels were told to clean and cement-wash their tanks and the tanks were inspected before fresh water was given them The water barges of the port are inspected daily Considerable quantities of imported food were condemned—of potatoes 100 tons onions 350, plums 50 all condemned vegetables were sent to the destructor: the animal food found unfit including 419 bags of mussels was made into manure. Shell-fish come mostly from the Zuider Zee (which is not as deep as a popular song asserts) and are officially certified to have been gathered from water free from sewage pollution Difficulty has been found in securing that railwaymen who handle fresh meat should wear washable caps and overalls, in accordance with the new regulations Insanitary defects were found in 7 per cent of the English ships inspected. but in only 5 per cent of the total of 8134 vessels Water-closets were choked on 109 ships side ports defective on 139, decks overhead leaking on 188 fresh water tanks dirty on 157 stoves and their fittings were defective on 145 Only 3702 beds were destroyed fewer than in the preceding year. Galley refuse on deck caused nuisance on 176 ships In accordance with the United States Quarantine Regulations 28 ships were fumigated with sulphur and, complying with another U.S. Order six lighters were disinfected for the transport of cattle feeding stuffs from mills to vessels for shipment to the United States (an export of some £800 000 in this year) Of 7813 aliens who arrived 3924 were transmigrants of whom 40 verminous were cleansed and 217 certified as suffering from trachoma favus or other infections The remainder non-transmigrants seem to have all been quite fit

Dr W F Dearden in his twentieth annual report to the *Manchester Port Sanitary Authority*, mentions tunities are likely to open in the future in connexion with maternity and child welfare; medical women with administrative ability are also needed for the inspection of women's hospitals and other medical institutions

Rates of pay are as follows —

Years of service	Overseas allowance per mensem	Salary per mensem	English equivalent* per annum
1 to 3	Rs 100	Rs 450	£440
4 to 6	,,	Rs 500	£480
7 to 9	,,	Rs 550	£520
10 to 12	,,	Rs 600	£560
13 to 15	Rs 150	Rs 650	£600
16 to 18	,,	Rs 700	£640
19 to 21	,,	Rs 750	£680
22 to 24	,,	Rs 800	£720
over 24	,,	Rs 850	£760

* At rupee value 1*s* 4*d*

Furnished quarters are provided, representing an additional Rs 150 per mensem

The cost of living in India is much higher than formerly, but it should be possible for a medical woman (with house provided) to meet actual household expenses for about Rs 200 per mensem, leaving the remainder of her salary for dress and personal expenses To this must be added the necessary saving to meet additional expense for furlough and leave spent in the hills

One month's privilege leave on full pay is granted each year. Furlough on half-pay at the rate of two months for every year of service is granted after every three years Study-leave on two-thirds pay is granted to the extent of 12 months in the total service There is a provident fund to which members of the service contribute 10 per cent of their pay The service contributes another 10 per cent which accumulates at interest and is repaid on retirement

Admission to the service is made by selection Candidates in the United Kingdom should apply to the Hon Secretary, United Kingdom Branch of the Countess of Dufferin's Fund, care of Major-General J. B Smith, India Office, Whitehall, London

MEDICINE AND THE LAW

Coroner's Duties under the Petroleum Act

IN the case of death from certain kinds of accidents a coroner is obliged by statute to adjourn the inquest unless a departmental representative is present to watch the proceedings Parliament made provision of this nature in the Metalliferous Mines Regulation Act of 1872, the Explosives Act of 1875, and the Coal Mines Act of 1911 The relevant part of the Explosives Act (Section 65) has now been applied with verbal alterations to deaths from accidents due to petroleum spirit, being re-enacted for this purpose as part of the Third Schedule to the new Petroleum Act which received the Royal Assent on August 4th last The coroner may, before adjourning take evidence of identification and order interment of the body If the accident has not involved the death of more than one person, and if the coroner has given the Home Office 48 hours' notice of the time and place of holding the inquest, he need not adjourn the proceedings if the majority of the jury think adjournment unnecessary If no representative of the Home Office is present and if there is evidence that the accident was caused by neglect or by a defect in connexion with any premises licensed under the Petroleum Act, or any carriage, ship, or boat in which petroleum spirit has been carried, the coroner must send the Home Office a written note of the neglect or defect Inspectors or persons employed by the Home Office are to have liberty to examine witnesses subject to the orders of the coroner upon points of law

A Death from Tetanus

Two boys were playing with a pistol at Leeds, they had a blank cartridge and some pellets, one of the boys let the trigger slip and three pellets entered the palm of his hand They then threw the pistol away and the injured boy told his parents he had split his hand by falling on a stone Two pellets were extracted by the boy's friends, but one remained in the hand The boy became ill, was removed to the Leeds Infirmary, and died of lockjaw The other boy, who was 15 years of age, was condemned by the coroner for having kept silence as to the cause of the accident "For a boy of your age to stand by and see a friend of yours die, when by telling the truth you might have saved his life, is appalling, and you deserve all the bad things that can be said against you" Coroners are seldom accurately reported, and in any case these remarks of the Leeds City Coroner presumably referred more to the moral than the medical aspects of the case Tetanus would not be suspected from the fact that the injury was due to a pistol shot, in fact, the false story of the fall upon a dirty stone would have been more likely to suggest tetanus infection.

Dangerous Drugs Withdrawal of Authorisation

The Home Secretary gives notice that he has withdrawn from Mr John Symington Stewart, M B, Ch B, of 252, Morrison-street, Edinburgh, the authorisations granted by the Regulations made under the Dangerous Drugs Act, 1920, to duly qualified medical practitioners to be in possession of and supply raw opium and drugs to which Part III of the Act of 1920 applies, and has also directed that the exception in Regulation 4 of the Dangerous Drugs Regulations, 1921, which permits dangerous drugs to be supplied on a prescription given by a duly qualified medical practitioner, shall not apply in respect of prescriptions given by Dr Stewart Any person supplying him with raw opium or any of the drugs to which Part III of the Act applies, and any person supplying the drugs on a prescription signed by Dr Stewart will be committing an offence against the Act

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 21st, 1926

Notifications —The following cases of infectious disease were notified during the week —Small-pox, 62 (last week 71), scarlet fever, 1163, diphtheria, 711, enteric fever, 54, pneumonia, 356, puerperal fever, 46, cerebro-spinal fever, 8, acute poliomyelitis 47, acute polio encephalitis, 6, encephalitis lethargica, 39, continued fever, 2, dysentery, 10, ophthalmia neonatorum, 114 There were no cases of cholera, plague, or typhus fever notified during the week

The notifications of acute poliomyelitis, which have been increasing in number steadily for several weeks, were received from all parts of the country Three were notified from the County of London, 4 from Chester (Crewe 2, Nantwich 1, Winsford 1), 1 from Devon, 6 from Essex (Grays Thurrock 5, Ilford 1), 6 from Kent (Gillingham 1, Queenborough 2, Sheerness 3), 6 from Lancaster (Blackpool 1, Manchester 1, Southport 1, Lancaster 2, Stretford 1), 6 from Leicester (Leicester 2, Barrow-upon Soar 3 Hinckley 1) 5 from Middlesex (Edmonton 1, Enfield 2, Hornsey 1, Willesden 1), 1 from Nottingham (Nottingham), 2 from Southampton (Portsmouth 1, Southampton 1) 2 from Stafford (Burton-upon-Trent 1, Stafford R D 1) 1 from Warwick (Birmingham), 1 from Yorks West Riding (Ripon R D), 3 from Glamorgan (Cardiff 1, Porthcawl 1, Rhondda 1)

Deaths —In the aggregate of great towns including London, there were no deaths from small pox none from enteric fever, 12 (0) from measles, 6 (1) from scarlet fever, 22 (2) from whooping-cough, 28 (10) from diphtheria 100 (18) from diarrhœa and enteritis under two years of age, and 16 (3) from influenza The returns for diarrhœa and enteritis show a rise of 15 for the great towns and a drop of 1 for London, compared with the figures of the previous week The figures in parentheses are those for London itself

INTERNATIONAL POST-GRADUATE MEDICAL COURSE IN BERLIN —Courses organised jointly by the medical faculty of the Berlin University, the Kaiserin Friedrich Stiftung für das Aerztliche Fortbildungswesen and the assembly of academic lecturers will be held in Berlin from Oct 4th to 30th They will include a course of instruction covering the advance of medicine as a whole with special regard to recent therapeutics a course in urology, and a course devoted to special departments of medicine Further information may be obtained from Kaiserin Friedrich-Haus, Luisenplatz 2-4, Berlin, N W 6 given hypodermically in suitable cases. Thirty-four nurses hold the certificate of the M.P.A.

The *East Sussex County Mental Hospital* at Hellingly had 1183 patients in residence on March 31st, an increase of 13 on the previous year, although the admissions were reduced by 19. The overcrowding will be lessened when the new verandahs and additions to the nurses' home are completed. Like Staffordshire, Sussex has tried to persuade boards of guardians to accept aged chronic patients in workhouses; a number of males will probably be accommodated in this way, but no offer to take females has so far been received. The general health has been good; there was some influenza, and two nurses and two patients had scarlet fever, but there was no dysentery. The death-rate was 9.7 per cent. for males and 7.9 per cent. for females. A large number of successful operations were performed, and the visiting surgeon has attended in consultation. The dentist held 50 sessions with 652 attendances. All new patients are seen by him as soon as they are fit. There was a recovery-rate of 31.8 per cent. for males and 36.9 per cent. for females; the prognosis of 44 per cent. of the cases admitted was unfavourable, this number including many senile patients, ten epileptics, and ten general paralytics. Sixty of the 132 patients discharged were sent out on trial, and 26 of them were given an allowance. One hundred patients have parole. Unlike the Stafford Hospital, Hellingly finds an increase this year in cases where alcohol was an exciting factor, the figures being 27 per cent. in men and 9 per cent. in women. All new cases are tested for the Wassermann reaction and 13 general paralytics were treated during the year by induced malaria. Five were discharged much improved and appear to be keeping well. The medical superintendent considers that the results fully justify the treatment, although the Wassermann reaction of blood and cerebro-spinal fluid has remained positive. In future it is proposed to employ antisyphilitic treatment as well as malaria. A well-equipped operating theatre and nurses' infirmary were added towards the end of the year. The diet has been improved. About half the male patients and 16 per cent. of the women are usefully employed, and the appointment of an occupation officer has been discussed. The medical superintendent, while admitting the value of such an official, agrees with the Leicester superintendent in observing that "the persons most likely to influence the patients are the nurses . . . and every endeavour should be made to encourage the nurses to take a personal interest." The ophthalmic surgeon saw 308 cases during the year, mostly for fitting with glasses. The pathologist, in addition to routine work and 50 autopsies, investigated the question of dysentery and carriers and found that the cases in the hospital were nearly always due to *B. aertrycke* or the Salmonella group. The blood calcium was estimated and found to be normal in all cases examined. A series of estimations of blood cholesterin suggest a hypocholesterinæmia in dementia præcox patients. The nurses have gained excellent results in their examinations, but there is still great difficulty in getting enough women for the work. This institution constitutes a good example of what a modern mental hospital can be. The Princess Alice Hospital out-patient clinic at Eastbourne is attended by the medical superintendent, but still has the handicap of being without beds.

POST-GRADUATE COURSES IN VIENNA.—Every year the Medical Faculty of the University of Vienna has arranged courses of lectures in German on all branches of medicine with a view to giving qualified doctors an opportunity of keeping in touch with the latest developments of medical science. In addition to these courses, four times a year, international post-graduate courses will be held in February, June, September, and November, and are particularly intended for visitors from abroad. Particulars of the courses to be held in the academic year 1926–27 are available in the form of a pamphlet which can be obtained gratis from the secretary of the Post-Graduate Medical Courses, Schlösselgasse 22, Vienna VIII. Advice as to lodgings will also be given on application.

Correspondence.

"Audi alteram partem."

NOMENCLATURE OF ABNORMAL UTERINE HÆMORRHAGE

To the Editor of THE LANCET.

SIR,—I notice in your account of the discussion on the "Causes and Treatment of Uterine Hæmorrhage without Gross Physical Signs" in the Section of Obstetrics and Gynæcology at the British Medical Association meeting (THE LANCET, August 31st, pp. 382 et seq.), and in a leading article in the same issue, that attention is called to the terms proposed for use in descriptions of disorders of the menstrual flow, and to aphysiological uterine bleeding. As a teacher especially, this is a matter to which I have given much thought, for students are readily confused by terms that are not absolutely clear. For years I have held that our special subject requires going over with a tooth-comb in regard to words so much abused as "endometritis" and with an axe for the abolition of meaningless terms like "metrorrhagia."

In the discussion in question, my friend, Prof. Beckwith Whitehouse, propounded the terms "epimenorrhœa," "menostaxis," "menorrhagia," and "metrostaxis" to cover the requirements of description in respect of various abnormal uterine hæmorrhages—namely, too frequent, too prolonged, and too profuse menstrual bleeding, and aphysiological hæmorrhages respectively. During the discussion the President of the Section "welcomed the *new* terms" (italics mine), and in your leading article the writer approves of "the terms proposed by Prof. Beckwith Whitehouse."

I am sure it has been merely an oversight on the parts of all these gentlemen that ten years ago (Eden and Lockyer's "New System of Gynæcology") and in the 1919, and if not in an earlier, edition of my own "Principles of Gynæcology," I introduced and explained the terms "epimenorrhœa" and "epimenorrhagia." I see no reference is made to "epimenorrhagia." Further, I stated that the word metrorrhagia should be abolished, for it was nonsensical and was used to describe various types of uterine bleeding by different persons. I employed the old term "menorrhagia" to include too profuse and too prolonged menstrual bleeding. This is what the word means; moreover, the two phenomena are usually associated. "Menostaxis"—used in America I believe, but I am away from home and all references—is a very poor and ill-defined word; it is quite unnecessary so long as we use menorrhagia in its proper sense, and it is likely to be confused by students with "metrostaxis." I sincerely hope no attempt will be made to perpetuate this terminological anomaly.

Lastly, I advised the use of the word metrostaxis—also an old term never properly defined—in the sense in which, so far as I can judge, it is advocated by Prof. Whitehouse, except that I should have spoken of "uterine hæmorrhages independent of *menstruation*" rather than of the "menstrual cycle." I am afraid Prof. Fletcher Shaw missed the whole point of this term. However, I do not wish to go over the old ground in relation to the pathology of the various conditions. It has so often been done already.

It follows then that the only "new" term proposed is one introduced by myself ten years ago and constantly advocated and taught since that time. Likewise, with the exception of "menostaxis," which should be discarded, the other terms were "propounded" certainly very clearly by myself, and possibly by others also in the distant past, and in a similar manner to that now welcomed as new. Still, all this is as nothing in comparison with the importance of the proper words being used in a uniform and correct sense. I trust that the publicity you have given to the matter will ensure this.

I am, Sir, yours faithfully,

Liverpool, Aug. 26th, 1926. W. BLAIR BELL.

that there was in 1925 no case of cholera, plague, or yellow fever, two cases of malaria and six of chicken-pox were treated on board ship; two cases of pneumonia and one of whooping-cough were treated on board canal boats As to rat destruction, 2240 rats were destroyed on board ships, 3116 ashore, none was found plague-infected Twenty-five ships were fumigated with sulphur, an average of 23 rats being killed on each Of meat from abroad, 7½ tons were condemned and seized, also 245 tons of vegetable food. Amongst the 2069 vessels inspected, 582 (28 per cent) had sanitary defects, there were nearly twice as many 20 years ago The defects of 351 ships were remedied before they sailed Of foreign-going steamers, 24 per cent had sanitary defects; of coasting steamers, 30 per cent The chief complaints were that fo'c's'les wanted cleaning and painting (131), that portlights were broken and defective (108), leakages on to the decks (40), water standing in the quarters (23), defects in water-closets (54), in the heating apparatus (49), and in the water tanks (23) Of canal boats, there are 811 under supervision; 70 had leakages into the cabins, of 66 the cabins were dilapidated and required repair, 41 required painting, while 32 had defective water casks, and 32 were overcrowded

---

MENTAL HOSPITAL REPORTS

THE *Carmarthen, Cardigan, and Pembroke Joint Counties Mental Hospital* at Carmarthen had 640 patients in residence on March 31st, 1926, this number being 47 in excess of the estimated bed-space The death-rate was 7 7 per cent, the cause being verified by post-mortem in only 10 per cent of the cases Influenza was prevalent in the spring and there were 12 cases of enteritis A wireless apparatus has been installed It is evident that the care and treatment of the patients is being carried on under peculiar difficulties in this hospital Improvements have been made during the year in the kitchen equipment, which will now provide much needed variations in the dietary scale, but the visiting commissioners were dissatisfied with the meals they saw served, as they were with the arrangements for producing milk on the farm The building is old and inadequately lit. The committee have under consideration the appointment of a dental surgeon, a measure which is of great importance and by now almost universal.

The *Down County Mental Hospital*, Downpatrick, had 727 patients on Dec 31st, 1925, and, unlike the majority of institutions in this country, had 73 vacancies, partly nullified by the use of certain wards for the nursing staff The recovery-rate was 43 6 per cent, a slight increase on last year The death-rate reached 5 9 per cent, the lowest figure on record for this hospital There was no zymotic disease. Post-mortem examinations were made in 13 out of the 37 cases; 60 per cent of the patients are usefully employed, over 100 on the farm, which made the satisfactory profit of £730 in the year In the shoe-maker's shop is made all the footwear for the institution (103 men and 42 women take exercise outside the grounds) The visiting dentist treated 372 patients and a consultant oculist attended when required The medical superintendent draws attention to the large proportion of mental derangements that arise outside the brain, every attention is here paid to disorders of the body Twenty-nine nurses hold their certificate and over 40 more are working for it The report is illustrated as usual by a number of excellent photographs We note the change of name from "Down District Lunatic Asylum"

The *Dorset Mental Hospital* housed 874 patients on March 31st and has ample accommodation for men, but there is shortage of female beds and of rooms for the nurses The death-rate was 5 5 per cent, a remarkably low figure, which may be partly due to the small number of admissions from general paralysis and epilepsy compared with other hospitals There were three cases of dysentery and one of typhoid fever The recovery-rate was 31 3 per cent Of the 100 cases discharged half were let out on trial and 20 were helped financially on discharge Nearly 100 cases are allowed parole and five wards are administered on the open door system A four-valve wireless set has been installed and an operating theatre has been equipped. There is also a new fire station and fire alarm system, a bathroom with continuous bath, and a modern telephone equipment The committee are considering the appointment of an occupation instructor In the laboratory the prevention and control of typhoid is being investigated, as there are six carriers in the hospital Thirty-one nurses hold their full certificate and 40 more have passed the preliminary examination An out-patient clinic is held at the Dorset County Hospital weekly and does valuable work

The *Staffordshire Mental Hospitals Board* have three hospitals At *Stafford* there are 961 inmates, which means that the work is handicapped by crowding, as also by the absence of verandahs, a convalescent villa and isolation blocks for tuberculosis The death-rate was 6 4 and a post-mortem examination was held whenever permission was given for it (58 per cent) There was a recovery-rate of 39 per cent The medical superintendent notes that alcoholism is not now nearly so potent an ætiological factor as it used to be Electric light and a wireless set have been installed and arrangements made for a mercury lamp for ultra-violet light treatment Twenty patients were allowed out on trial, but no money grant was made Parole within the estate is allowed to 13 patients Only 16 nurses hold the M P A certificate At *Burntwood* there are 914 patients The death-rate was 7 9 per cent., post-mortem examinations were held in 90 per cent of cases There were three cases of rubella during the year, but no dysentery and only a little influenza The hospital is crowded on the male side, and the committee propose to erect an admission hospital and a convalescent villa when they can afford them An attempt to relieve congestion by transferring quiet chronic cases to the care of the guardians was not successful, as the boards refused to accept the cases Twenty-seven patients have been discharged on trial and a weekly allowance is now given, 20 cases have parole in the grounds and 14 beyond The dental room has been remodelled and is used for operations Two cases of general paralysis have been treated by malaria and have benefited In the pathological laboratory the relation between acidosis and epilepsy has been investigated Fifteen male nurses, but no females, have the M P A certificate At *Cheddleton* there are 1123 cases and the hospital is full Not only is there need for more mental beds, but the medical superintendent estimates that a colony providing for 1500 mental deficients would not be too large for the requirements of the area There are nearly 100 of these children in Cheddleton, an orthopædic consultant attends weekly and a trained masseuse has begun work on muscle re-education, but, as the superintendent remarks, it is "desperately slow work" Satisfactory results have followed the treatment in several cases A travelling organiser of the National Association for Mental Welfare spent a month working out a time-table suited to the mentality of the children, but there is great difficulty in getting nurses with sufficient patience and devotion to teach the low-grade classes Plans have been submitted for a children's block as their health is unsatisfactory in wards without verandahs Among the adult patients there were several cases of influenza and of dysentery, but no carrier was found The death-rate was 9 2 per cent Eight general paralytics have been treated by induced malaria, two have improved and one man has been back at work for five months A cinema room and second laboratory are nearly completed Eurhythmic dancing and Swedish drill classes have been started and an electric installation provided for diagnosis and treatment Plaster has been used instead of splints for fractures, and endocrine gland products are being of Philoctetes, in the play of that name, Sophocles had in his mind the symptoms which characterise a malarial attack. The periodicity, the shivering, ingravescence, and crisis followed by sleep with sweating, and a transient feebleness on waking, offer a clinical picture of peculiar vividness' This suggestion was accepted by Allbutt and Osler In other of his extant plays Sophocles appears to show a very special interest in the clinical features of disease which may be correlated with the fact that he is known historically to have been closely associated with the cult of Asklepios, for after death he received the hieratic title of "Dexion"—i e, "The Receiver"—from the fact that he became the official host of the statue of the hero-physician when this was brought to Athens from Epidaurus in B C 421

The object of my paper was an attempt to show that in his conception of the madness of Ajax, Sophocles displays a remarkably accurate knowledge of the clinical features of acute confusional insanity It is not true, however, as I am reported to have said, that "the accuracy of this description has been praised by many writers," for, so far as I am aware, no previous writer has drawn attention to this clinical aspect of the writings of the tragedian who "saw life steadily and saw it whole" Incidentally, it may be remarked that this accurate description of madness which appears to be based on actual experience stands in marked contrast to the conventional delineation of insanity given by Euripedes in his "Mad Hercules" The plays of this poet are, however, of great interest to students of psychology, for they are characterised by a very clear understanding of the phenomena of repression and by a remarkable insight into the problem of conflicts and complexes Indeed, had he lived to-day, it is probable that Euripedes would have been an earnest disciple of the psycho-analytic school

I am, Sir, yours faithfully,

Birmingham, August 27th, 1926 G A AUDEN.

ERYSIPELAS AND NEPHRITIS.

To the Editor of THE LANCET

SIR,—After reading the interesting lecture of Prof. Cabot on non-tuberculous infections of the kidney in THE LANCET of July 10th, I shall be obliged if any of your readers will inform me whether they have come across cases of chronic nephritis after an attack of erysipelas It is, of course, well known that people who suffer from Bright's disease are liable to attacks of erysipelas During my 25 years' experience in Bombay I have noted about 20 cases of chronic nephritis which developed between 18 months and two years after an attack of erysipelas I am led to believe that just as acute nephritis frequently follows scarlet fever, chronic nephritis of the interstitial variety follows erysipelas after remaining latent for many months —I am, Sir, yours faithfully,

C L D'AVOINE, M D Brux.

Bombay, August 4th, 1926

CHENOPODIUM FOR ANKYLOSTOMIASIS

To the Editor of THE LANCET

SIR,—With reference to Dr Clayton Lane's interesting and authoritative article on the Treatment of Ankylostomiasis in THE LANCET of August 14th it may be of interest to your readers to remind them that until this year it has not been possible to issue a chenopodium oil answering Dr Lane's requirement that it should be of known ascaridole content because no trustworthy direct method of estimating ascaridole in the oil was known Such a process has however been described by Mr H Paget, of the Wellcome Chemical Research Laboratories in a recent number of the *Analyst* (1926, li, 170) and this has been tried by our analytical department and found satisfactory For some years past we have issued for use in ankylostomiasis a concentrated chenopodium oil prepared by a new process This was known to be particularly rich in ascaridole and, tested by the new analytical method, it is found to contain not less than 90 per cent, whereas as Dr Lane points out, ordinary chenopodium oil may vary from 50 to 70 per cent in ascaridole content a variation which involves risk of overdosage—We are Sir, yours faithfully,

BURROUGHS WELLCOME & Co.

Snow Hill Buildings London, E.C 1,
August 18th, 1926

CLINICAL PATHOLOGISTS AND "CHORIOTROPE"

THE Hon Director of the Liverpool Cancer Research Committee writes that it is proposed to hold in Liverpool clinics and demonstrations of the methods employed there in the treatment of malignant disease, for clinical pathologists attached to clinics and hospitals of standing, in order that they may have the opportunity of studying at first hand the details of this work

Subsequently "choriotrope" will be obtainable for use in the treatment of the patients of those who are attached to the clinics concerned It is suggested that the clinical pathologists who attend the demonstrations make themselves responsible for the full and proper conduct of the examinations required in every case subsequently treated under their guidance, and that no publication regarding results be published for, say, five years

It must be understood that the entire clinical staff of the Liverpool Cancer Research Organisation is on a part-time basis and, therefore, that members cannot place themselves at the disposal of those attending, nor can these demonstrations be repeated except at long intervals and then only to limited numbers. Consequently it may be necessary for a selection to be made from those applying if there be too many at one time A certain number of invitations have been issued to those who have already expressed a desire to attend, but a few further applications are still invited

The demonstrations will be chiefly conducted by Dr Leslie Cunningham, assistant director of the Organisation, and will commence at 10 A M, Monday, Sept 6th, and continue until Wednesday Sept 15th

---

A RAILWAY HOSPITAL FUND.—Last year the staff and directors of the L.M S Railway contributed £136,000 to the Company's Hospital Fund, and it is hoped that £150,000 will be reached this year The majority of the staff, numbering about a quarter of a million, gave twopence per week, which is deducted from their pay, and the directors another penny Membership of the fund entitles to admission to any hospital in the country for the man himself, his wife and children

TRELOAR HOSPITAL.—The report of the Lord Mayor Treloar Cripples' Hospital and College at Alton and Hayling Island records a year of steady progress There has been a marked increase in annual subscriptions and although the total expenditure has increased there has been a substantial fall in the cost per patient. There are now 350 beds 40 of which are being set aside for general orthopædics Sir Henry Gauvain's medical report comments upon the growing demand on beds for sufferers from lupus which necessitates constantly increasing work in the light department and points out that the hospital now concentrates almost entirely on the treatment of tuberculous cripples The children admitted from Portsmouth for whom, by agreement with the Portsmouth Education Committee special provision is made, have been cases of severe and old-standing deformity but up to the present the results of treatment have been quite satisfactory It is found that climatic change associated with sea bathing and natural sun treatment is more effective than uninterrupted treatment in the light department During the year 216 physicians and surgeons from all parts of the world visited that department and a large number remained to study the technique employed The result of the investigations of light therapy by Dr Bannerman the research pathologist is to emphasise the risks of over-dosage Thanks to the generosity of Sir Horace Plunkett and the Medical Research Council Dr Bannerman's services are being retained for another year

THE TREATMENT OF MENORRHAGIA

To the Editor of The Lancet

Sir,—In the recent discussion at the British Medical Association, and in your leading article of August 21st, it is surprising to find no mention of the method of intra-uterine ionisation for the treatment of obstinate menorrhagia Electrotherapists have long known of its efficacy, even in cases which have resisted every other method by drugs and endocrine preparations, and even curetting In 1917 the late Dr Samuel Sloan drew attention to the fact that copper ionisation cured almost every case of menorrhagia, except that arising from fibroids Over 20 years ago Dr A E Zimmern, of the Salpêtrière, published a large book on the subject, giving minute details of many cases of every type Dr Zimmern described his method and showed his instruments in London in January, 1922, at a meeting[1] of the Electro-Therapeutic Section of the Royal Society of Medicine His good results were confirmed by the experiences of several of the English electrotherapists present at the meeting In the *Practitioner* of July, 1921, I described fully the case of a young girl of 23 who was sent to me for ionisation as a last resort by the gynæcologist who had already twice curetted her It may be objected that intra-uterine ionisation is difficult to employ in virgins, but its use is not more complicated than the introduction of radium, and has at least the great advantage that it can never cause sterilisation

I am, Sir, yours faithfully,
Agnes Savill

Devonshire-place, W, August 27th, 1926

THE TECHNIQUE OF BLOOD TRANSFUSION

To the Editor of The Lancet

Sir,—In the course of his article on this subject in your issue of August 21st Dr P C Gibson is good enough to refer in favourable terms to the apparatus described by me in 1920 He claims, however, now to have introduced various improvements into the apparatus I may be allowed, perhaps, to express a doubt as to whether Dr Gibson's additions really are improvements I should view them as unnecessary complications which will in no way render blood transfusion easier of performance, but rather the reverse

The defects in my original apparatus he regards as being (1) the risk of contamination of the blood because the mouth of the flask is not closed by a bung, (2) the liability to the formation of a clot in the tube during the collection of the blood I dispensed with the bung in my apparatus because, with the tube hanging freely into the flask, the needle seemed to be less likely to be dislodged from the donor's vein by the movements of the flask during the mixing of blood and citrate At least one junction between rubber and glass tubes was also eliminated The risk of contamination of the blood by "infective material" falling into it I regard as a purely academic point which need not be considered by any competent operator

As regards the second point, I can only state that, during eight years' experience of the apparatus since I first used it, I have not been troubled by this supposed defect If the ordinary technique is properly carried out the rate of flow of the blood is quite as fast as most donors can stand without fainting Very occasionally a clot forms in the *needle* (never in the tube) before all the blood is collected if the amount needed is rather large Should this happen the remainder of the blood can easily be taken with a second needle from another vein Dr Gibson's additions will not prevent a clot from forming in the needle

Lastly, Dr Gibson's device for running in the citrate solution with the blood apparently results in his using nearly five times as much sodium citrate as is really necessary I understand that he uses 4 5 g of citrate for each 400 c cm of blood My own practice is to use 1 g of citrate for each 450 c cm of blood, and with the ordinary technique this need never be exceeded

I must apologise to Dr Gibson for thus criticising his apparatus, but I do so only in the interests of patients and operators If transfusion is to be used to full advantage the apparatus required must be as simple as possible and in view of the possible toxicity of more than a small quantity of sodium citrate the amount injected into the patient must be as small as possible —I am Sir, yours faithfully,

London, August 23rd, 1926 Geoffrey Keynes

THE PATHOLOGICAL SERVICE OF THE GENERAL HOSPITAL

To the Editor of The Lancet

Sir,—In your issue of August 14th Dr Dyke has some suggestions as to the relation of the hospital pathological department to outside practice In connexion with this I ask again as I have asked before Why should hospitals and universities compete with pathologists in their private practice when they do not do so with clinicians? It is a pitiful thing to see clinicians encouraging this competition with pathologists when they would not think of encouraging a similar competition in their own branches of medical practice Pathologists are consultants as much as are other specialists and should be treated as such

Dr Dyke apparently suggests that the hospital should undertake the outside work and should derive an income from it, paying part of the fees to the pathologist Such a scheme is, in my opinion, unfair to the pathologist The only way in which hospitals, &c, could fairly take part in outside pathological practice is somewhat on the following lines The hospital could —

(1) Provide and equip a laboratory in the hospital precincts,

(2) Pay a stipend to the pathologist to cover all work done for the hospital or, alternatively, pay the pathologist a retaining fee and agreed fees for hospital work, the hospital work, in either case, to take precedence over private work,

(3) Allow the pathologist perfect freedom to make his own arrangements as regards private practice and work for outside authorities,

(4) Allow the pathologist the use of the laboratory for private purposes on payment of expenses and a reasonable rent

The relation of the pathologist to outside work would thus be a personal one He would decide on the fees to be charged and would pay the hospital for expenses and rent The only income which the hospital ought to receive from outside work is that paid as rent by the pathologist It is iniquitous that a hospital should make an income out of the private practice of a member of its staff If the hospital pathologist were granted this independence there would be an inducement for him to settle down permanently in pathological practice

It is quite time that pathologists should combine to resist the idea that they are the tools of the clinicians —I am, Sir, yours faithfully

Charles Powell White

Manchester, August 16th, 1926

SOPHOCLES AND CONFUSIONAL INSANITY

To the Editor of The Lancet

Sir,—In the short résumé of a paper on the Madness of Ajax as Conceived by Sophocles, read before the Royal Medico-Psychological Association, which was published in The Lancet of July 24th (p 177), I am represented as maintaining that "in his delineation Sophocles probably had in mind an attack of malaria" This is however a complete perversion of the theory which I maintained but is clearly a reference to a suggestion which I put forward many years ago that in his description of the sufferings work, and a hearty capacity for sympathy with all other workers whatever their grade when he came into relation with them. In the Canadian metropolis, while he carried on his professional duties and acted as advisory pathologist to the two great hospitals of the city, he found time to preside over the Montreal Improvement League and the various organisations in behalf of child welfare. and throughout his tenure of the chair in Montreal he was a prolific and also a valuable contributor to scientific journals and the transactions of learned societies. He was elected F.R.S. in 1905, and it was at Montreal that he began to attract wide attention by his writings.

---

[1] The Lancet, 1922, i, 178

Adami was an original contributor to Allbutt and Rolleston's "System of Medicine," where his article on inflammation was recognised as an outstanding feature in the commencement of that great compendium, but shortly he made a claim upon individual notice by his great text-book of pathology. The "Principles of Pathology" appeared in 1909. and all Adami's special qualifications for its writing were put into evidence. His training had been wide, as has been indicated, for he had worked with Roux in Paris, with Heidenhain in Breslau, and with Michael Foster and Roy, among others, at Cambridge; he essayed boldly, and with a clear and forcible pen an exposition of a science which had spread and was rapidly spreading from the realms of morbid anatomy, and changes in cell histology, to the study of cellular function in disease and its basic disturbances. The result was a work which was catholic in its range and critical in its presentation of the prominent problems of the day, and as such it was acclaimed as the best British compendium of general pathology that had yet appeared. No second edition of these two massive volumes was published. Their success would have justified their regular appearance brought up to date, and expanded or contracted in accordance with the development of the science, but the inclusive nature of their range would have necessitated for such a purpose the cooperation of a band of special workers, and would have altered the whole original conception. But four years afterwards there appeared the Text-book of Pathology by Adami and his colleague at McGill University, John McCrae. This was a single volume within whose covers it was endeavoured to embody the features of the former work and to follow its main lines, but in the large section dealing with special pathology it was found necessary to write without any reference to the earlier work. The treatise by Adami and McCrae became rapidly popular, has been issued in revised and enlarged form, and many of our readers have been grounded in their work through its assistance.

In 1918 Adami published a series of Medical Contributions to the Study of Evolution, the first part of the volume consisting of the Croonian lectures which had been delivered the previous year before the Royal College of Physicians of London and published some in full and some in abstract, in the columns of THE LANCET. This volume was directed rather to the biologist than to the medical man, and in its pages the author called attention in an uncompromising manner to the unsatisfactory state of biological opinion on the problems of variation and adaptation. His main thesis was that congenital adaptation is not really different in kind from individual adaptability, and that as the individual adapts itself directly to changed environment so does the species give rise to germinal variations of an adaptive nature when the environment is such as to call them forth. Later papers in the book were not up to the standard of the Croonian lectures and, though the volume was full of valuable information and reflection, it was felt that there were contentious passages which the author himself would have removed had the times in which he was writing been leisurely instead of over full with the troubles of the war.

We are indebted to an authoritative source for the following estimate of Adami's place as pathologist and author:—"James Ritchie used to urge all his pupils to 'read Cohnheim,' which is easy to do in the three volumes of the Sydenham Society's translation of the 'General Pathology.' And reading Cohnheim is still probably about the most profitable introduction to the serious study of pathology, not so much for what he says (though that is important and still for the most part true enough) as for the tone and manner in which he shows how the principles of pathology may be traced out and woven together into a scientific study. But Cohnheim is long and students are impatient; if a teacher wants more than a few of them to get the right idea of how they should approach the post-mortem room, the classroom, and the wards it is better to press upon them Adami's article on Inflammation in Allbutt's System of Medicine, which is also published as a small book. They will find here equally well and much more briefly, an illustration of how they should think about disease and learn the outlook on pathology which made Adami the influence which he has been. It is not very remarkable that the two books should be akin. Cohnheim trained Smart Roy, and it was with Roy at Cambridge that Adami did his first serious research, familiar to physiologists as 'Roy and Adami: The Physiology and Pathology of the Mammalian Heart' (*Phil. Trans.*, 1892, vol. clxxxiii., B, p. 210). After Adami went to Canada in 1892 as the first professor of pathology at McGill he was not much given to doing laboratory work himself. He developed the department founded by Osler—who began by holding morbid anatomy classes in a cloakroom—and became interested in the possible relation of intestinal bacteria to cirrhosis of the liver. A variety of contributions to the pathology of the heart and especially the blood-vessels came from his laboratory, but he is probably best known for his classification of tumours (*Journal of Pathology*, 1903, vol. viii., p. 243) which provided a convenient arrangement of pigeon-holes into one or other of which most tumours could be fitted. It scarcely did more than this when it was published, and subsequent knowledge of the varied potentialities of cells has made the embryological basis on which it was founded insecure. What Adami will, however, be remembered for and remembered gratefully, is the first volume of the 'Principles of Pathology,' in which his studious life and wide biological training found expression in 1909. It is an attempt to develop pathology as a science. As he points out, books giving a presentation of pathological data were many and excellent, but 'what is needed in a text-book of pathology is not the mere record and description of phenomena, but the attempt to analyse these phenomena in an orderly manner,' and to bring them into relation with other branches of biological study—to do, in other words for the whole of the subject what he had already done for inflammation. The attempt may not be wholly successful, and the second volume on systemic pathology has nothing to distinguish it from several other text-books. But the book does not fall really short of being a great work and it certainly deserves to have been used much more than it has been, for it was never very popular and instead of being trimmed and improved in successive editions it has now practically gone out of sight. Perhaps it was written too early, and an audience which wanted diagnosis and names was impatient of its philosophic tinge or perhaps it has had more influence than is obvious. In Adami's old university Prof. Dean has begun the first course in advanced pathology in the Natural Science School along lines adumbrated by Adami, and at Montreal Adami's successor does not hesitate to weave classical philosophy into his pathological discourses. Adami's views were sound and in the end will prevail; it is only in some small way that he missed being a more effective missionary himself. Meanwhile those who would get an idea of his mind without too much technical detail should read the 'Medical Contributions to the Theory of Evolution.'"

During the war Adami served in the Canadian Army Medical Corps with the rank of colonel. He was eventually made Assistant Director of Medical

The Services.

RETIREMENT OF SURGEON REAR-ADMIRAL BEADNELL.

Surgeon Rear-Admiral C M Beadnell, C B, is retiring at his own request, thus facilitating the promotion of his juniors. He had reached the top of his rank, there being no further employment for a surgeon rear-admiral after the completion of three years' full-pay service in that position, save selection as Director-General He is five years under the age-limit owing to early promotion for good service, a fact which unfortunately will be reflected in his pension

ROYAL NAVAL MEDICAL SERVICE

The following appointments are notified Surg Lts E T S Rudd to *Royal Sovereign*, H Gow to *Ajax*, J M MacWright to *Victory*, for R N Hospl, Haslar, for 14 days' training, W F. Lascelles (proby) *to Victory*, for R N Hospl, Haslar, for 28 days' training, and J L Cox to *Erebus*, for 14 days' training

Surg Comdr M J Laffan, appt to *Malaya* cancelled

Surg Comdr T E Blunt is placed on the Ret List at his own request with rank of Surg Capt

The following promotion has been made —Lady Superintendent to be Chief Lady Superintendent. Miss W Walker

Obituary.

JOHN GEORGE ADAMI, C B E, M D CAMB, F R C P LOND, F R S,

VICE CHANCELLOR OF THE UNIVERSITY OF LIVERPOOL

WE regret to announce the death of Prof Adami, Vice-Chancellor of the University of Liverpool, which took place in a nursing home in Liverpool on Sunday evening last in the sixty-fifth year of his age His health had given cause for anxiety for two years, an improvement which took place a short period ago was not maintained, and for several weeks there had been little hope of his recovery

John George Adami was the son of a Manchester man bearing the same name, and his mother was the sister of Prof D J Leech, the well-known Manchester pharmacologist This association with Manchester was maintained by education at the Grammar School and at Owens College, whence he proceeded with a scholarship to Christ's College, Cambridge, to take a first class in the Natural Science Tripos and be also Darwin Prizeman Then he studied abroad for a time both in Paris and Breslau, and, having graduated in medicine at Cambridge, became house physician to the Manchester Royal Infirmary At the termination of his residency he returned to Cambridge as demonstrator of pathology, was awarded the John Lucas Walker Studentship, and was elected a Fellow of Jesus College At Cambridge he worked particularly under Smart Roy, and their combined observations in comparative pathology established his reputation as a coming man He was just 30 when, in 1892 he accepted the position of Strathcona Professor of Pathology and Bacteriology at McGill University, Montreal He immediately began to earn a name for himself by his clear and thorough methods of dealing in class-room and laboratory with the simple and with the advanced sides of his subject, as well as by his general *outlook upon* scientific education As time went on he displayed the qualities which afterwards were *notable* in Liverpool his intellectual capacity being combined with a great aptitude for business *routine*, a robust appetite for

J G ADAMI

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated :—

Surgery—A. K. A. Carter, Univ Coll. Hosp ; M. E M Carter, Univ Coll. and St Mary s Hosps C E. Nicholas, London Hosp , J Pattis, Innsbruck and Univ Coll. Hosp. ; A. Purvis, Durham , M. Stinnisbeck, Freiburg and Royal Free Hosp , and N W Wood, Middlesex Hosp

Medicine.—J Dywien Guy s Hosp ; R. C Glover, Leeds and St. Bart.'s Hosp , K. G B McMahon, Charing Cross Hosp , T. C Pain Guy's Hosp , P H Row and L Schapera, London Hosp , R. S S Smith St Bart 's Hosp , J A. H. Sykes, Edinburgh , and L. D Williams, Cardiff.

Forensic Medicine—N. H. Allen, Guy s Hosp F. W Barton, Middlesex Hosp . S B Browning, Guy s Hosp , M. E. M. Carter, Univ Coll. and St. Mary's Hosps , F G Hardaker, St. Mary's Hosp C E. Nicholas, London Hosp K. Roberts Liverpool L D Williams, Cardiff , and N W. Wood, Middlesex Hosp

Midwifery—C B Ball, Sheffield ; A. Heukamp, Gottingen and Royal Free Hosp , W Hinds, Durham ; S Jenkinson, St. Bart s Hosp , H S. Littlepage, Birmingham ; J. B Lurie, St Thomas's Hosp . A. Purvis, Durham ; R. J Richards, St George s and St. Bart 's Hosps : T W Riseley, Cardiff , and J M. F. Whitby, St Thomas's Hosp

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery N H Allen C B Ball, A. K. A. Carter, W. Hinds, J B Lurie, K. G B McMahon, T C Pain, A Purvis, P H Row, L. Schapera, M. Stinnesbeck, J A. H. Sykes, and J M. F Whitby

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION—Each week the City of London Maternity Hospital holds a course in obstetrics, including ante- and post-natal clinics and children's welfare clinics Personal application to attend this course must be made to the Secretary of the Fellowship During September courses will be given as follows At the Central London Ophthalmic Hospital from Sept 6th to Oct 2nd, occupying the whole of each afternoon , at the Bethlem Royal Hospital, the course taking the form of lecture-demonstrations on Tuesdays and Saturdays at 11 A.M. from Sept 7th to Oct. 2nd ; at the Infants Hospital, from Sept 13th to 25th, occupying every afternoon and including one Sunday visit to Thavies Inn V D Centre , at the Royal Free Hospital, where Dr. C B Heald will give four lecture-demonstrations on treatment by electrotherapy on successive Wednesdays at 5 15 P.M., beginning on Sept. 22nd , at the Royal National Orthopædic Hospital, *from Sept 20th to Oct* 2nd, where a comprehensive course in orthopædics will be given covering all branches of the subject and occupying all of each day. Finally, there will be an intensive course in medicine, surgery, and the specialties at the Westminster Hospital, from Sept. 20th to Oct. 2nd, from 10 30 to 5 30 daily Early in October the National Hospital for Diseases of the Heart will give a fortnight's course Entries are limited to 16 so early application is advisable. Other courses starting the first week in October are as follows : a series of demonstrations on Tuesday and Thursday afternoons at the London School of Tropical Medicine and an all-day course in diseases of the throat nose and ear at the Central London Throat Nose and Ear Hospital, where there will also be a practical operative surgery class Copies of all syllabuses of the General Course programme. and of the *Post-Graduate Medical Journal* may be obtained from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

THE LATE DR. D E FLINN—On August 18th the death occurred at Kingstown co Dublin, of Dr David Edgar Flinn, who was well known for his interest in the medical aspect of reformatories and prisons Dr Flinn was born in 1850 at Buenos Ayres, and educated at Clongowes College, the University of Dublin and the Royal College of Surgeons in Ireland. He qualified in 1874, becoming M R C.P I in 1882, F.R C S I in 1885, and D P H in 1890 For a time he acted as medical officer of health to the East Staffordshire urban and rural combined districts and from 18[illegible] to 1901 was editor of the *Health Record*. During this period he published several books on public health subjects, and in 1893 served on the Dublin Typhoid Inquiry Committee. In 1907 he was made a member of the Vice Regal Commission appointed to inquire into the causes of the high death rate in Belfast From 189[illegible] to 1910 Dr Flinn was medical inspector of the Local Government Board Ireland and from 1910–17 a medical member of the Prisons Board and chief inspector of reformatory and industrial schools Though he had long retired from active participation in the attempt to improve prison conditions, he followed the modern developments in this direction with keen interest, though not always with approval Dr Flinn was an enthusiastic Volunteer and later a Territorial attaining the rank of colonel before his retirement in [illegible].

ST. MARY'S HOSPITAL—The annual dinner of past and present students will take place at the Connaught Rooms, Great Queen-street, London W.C , on Oct. 4th at 7.30 P.M. Dr G W H. French will be in the chair, and the hon. secretary is Dr. A. Hope Gosse.

ROYAL SANITARY INSTITUTE.—The thirty-eighth congress and health exhibition of this institute will be held at Hastings from July 11th to 16th, 1927, under the presidency of Sir William Joynson-Hicks.

WESTMINSTER HOSPITAL—The report for the first complete year since the reconstruction of the building states that there has been a remarkable increase of work in every department and that 221 out of the 234 beds have been constantly in use. The X ray and electrical department treated 3655 patients and the private wards were now occupied by 206 patients Annual subscriptions increased by 58 per cent , and patients paid £19,000, including £6000 from those in the private wards

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—The annual dinner of past and present students will take place in the Royal Adelaide Gallery, Gatti's Restaurant, Strand. W C 2, with Mr William Turner in the chair, on Friday, Oct. 1st, at 7 P.M.

GUY S HOSPITAL.—Of £167,000 received by this hospital in 1925, £64,000 was from endowments Subscriptions produced only £5000, which leaves nearly £100,000 to be obtained from other sources The bicentenary appeal to relieve the hospital and medical school of debt produced nearly £90 000, which is less than had been anticipated. The average stay of the 10,395 in-patients was 20 days and their cost £11 10*s* 9*d*.

KING'S COLLEGE HOSPITAL: RE-OPENING OF WARDS—Last week two small wards containing between them 34 beds were reopened a course justified, from the financial point of view, by a drop of 5*s* 8*d*. per week in the cost of maintaining a patient. One-half of the liberated beds have been assigned to the nose, throat, and ear department, which has the longest waiting list

SHEFFIELD HOSPITALS.—The annual report of the Sheffield Hospitals Council, which has just been issued, shows that on Dec. 31st. 1925, the four Sheffield voluntary hospitals were in debt to the extent of £102,000. During the year 20,886 new contributors joined the "Penny-in-the-Pound" Fund, and the amount received from employers and workpeople exceeded £107,000 A total number of 44 000 casualties were treated The council's most urgent problem is that of giving early admission to the large numbers on the waiting lists

POST-GRADUATE HOSTEL.—On Tuesday, August 17th with Dr L. Long (Oklahama) in the chair, Mr. Donald Armour opened a discussion on Head Injuries He pleaded for an ipsolateral decompression in all cases of compression due to injury as the patient was too ill to deal with the cause, moreover even symptoms from contrecoup would often prove amenable. He deplored the present methods of cerebral topography. Lumbar puncture was valuable in treating traumatic neuroses, but was dangerous in the presence of high intracranial pressure due to the possible formation of a "pressure cone." Trephinings for decompression should be large During discussion Dr Long emphasised the importance of prolonged rest after head injury if sequelæ were to be avoided. On Thursday (August 19th) Dr Harold Scott pathologist of the Zoological Society, opened a discussion on Some Points on Tuberculosis among Wild Animals in Captivity, Dr Simpson Wells (Cape Town) being in the chair Dr Scott said that tuberculosis took on different characteristics in animals birds, and reptiles, and it was important to consider that they were intercommunicable Dr Wells, in the discussion said that Macewen's theory that tuberculosis nearly always started in childhood later appearance being far more fatal found an analogy in Dr Scott's statement that wild animals only suffered from tuberculosis when placed in captivity. The disease was then very fatal and was found in an advanced stage when the animal had appeared healthy

In the coming week on Sept. 8th Mr. A. Rocyn-Jones will open a discussion on Manipulative Surgery and the Bone-setter On the following day Dr G Clark Trotter will open a discussion on the General Practitioner and the Medical Officer of Health These discussions will take place at [illegible] P.M. at the rooms allotted to the hostel at the Imperial Hotel Russell-square London W C No introduction beyond the presentation of a visiting card is required and there is no entrance fee or subscription.

Services, was appointed to the War Office Committee on the Medical History of the War, and became the historical recorder of the medical services of the Canadian Expeditionary Force His history, the first instalment of which appeared in 1918, was based as much upon the diaries of individual medical officers as upon official documents, and aimed at giving the professional reader a bird's-eye view of the development of military medicine as exemplified by the work of the C A M C. A mere list of the historic events which passed under Adami's notice would show how deeply interesting his volumes are Four short chapters in the first volume give, for example, the medical history of the second battle of Ypres, and are noticeable for a moving description of the introduction of poison gas, the C A M C being the first corps to incur the terrible experience The corps were fortunate in their biographer, for Adami was not afraid to call attention to defects in the official records, while he supplied an interesting historical background to events which are detailed as episodes in a great adventure He was appointed C B E. in 1919

Adami did not return to Montreal after the war, but accepted the post of Vice-Chancellor of the University of Liverpool on the retirement, in 1919, of Sir Alfred Dale, and speedily justified his choice He did little more scientific work, though both in writing and in public speaking he ever displayed keen interest in research and a laudable receptivity in regard to the teachings of his successors He concentrated on the official side of his duties He had the personal appearance rather of a man of affairs than of a student, and in that capacity he showed himself successful He brought University affairs unceasingly to the notice of Liverpool to the considerable benefit of the finances of the institution, and to the benefit of the citizens also who were taught to use as well as appreciate the opportunities offered by a centre of education in their midst If he was not always judicious in his many public utterances, his indiscretions were clearly due to his enthusiasm that had the greater chance through public comment of becoming contagious In all Liverpool circles and in all grades of the University his active and stimulating personality will be sincerely missed "At the age of 64," writes our Liverpool correspondent in appreciation of a dead friend, "Adami was still carried forward by an eager interest in all that concerned the welfare of the University in its widest aspect, and he still found time, in spite of multifarious public duties, to read papers on scientific and literary subjects, and to join in the activities of widely varied interests designed to advance the public weal It is true that for the last two years his health has not been equal to the strain, but the spirit remained undaunted, shone out in a glowing face, and was betrayed by an ever-hurried gait It is recognised by all that, especially in these last seven years, Adami has done a great work for Liverpool by getting rid of that isolation from the life of the community, which is so apt to mark, and mar, the existence of newer universities With the students the Vice-Chancellor was a very popular figure, and to see him at their gatherings, his face beaming with enjoyment over some humorous piece of byplay or some quieter sally of his own, was in itself a great delight He entered very fully into their interests and spent himself freely when he felt his influence or action was needed in their behalf In later years he had been feeling the necessity for the more general and systematic cultivation of health as a vital activity of the University amongst its undergraduates By all with whom he came in contact he will be mourned, by his colleagues and his students no less than by the prominent men in the civic life of the city on whom he had made a deep impression Still deeper, of course, will be the loss to those who were his personal friends They best knew how he could blend with his sterling qualities a happy almost sprightly spirit whose influence it was impossible to resist"

Adami received, as might be expected, and in addition to those already mentioned, many academic honours He was an honorary F R.C S Eng, and was similarly complimented in Scotland and Canada, he was an honorary M D of three universities, an LL D of three more, and a Sc D of Trinity College, Dublin He was a Fellow both of Jesus College and his own college (Christ's), he was a past President of the Association of American Physicians, and Fothergillian Medallist of the Medical Society of London

He was twice married, first to Mary, daughter of J A Cantlie, of Montreal, by whom he had two children, and, secondly, four years ago, to Marie Wilkinson, daughter of the Rev Thomas Wilkinson, vicar of Litherland, who survives him

---

Donations and Bequests —Under the will of the late Mr Jeremiah Edward Bles, M A., D Sc, F R C S, of Cambridge, the testator left all his scientific instruments, scientific books, and the fittings and contents of his private laboratory to the Chancellor, masters, and scholars of the University of Cambridge, and he empowered his trustees to expend a sum not exceeding £500 in completing any researches made by him and publishing the results of any researches not published at the time of his decease Failing issue who shall attain an interest, and subject to his wife's life interest, he left the residue of his property, after certain bequests, to the Chancellor, masters, and scholars of the University of Cambridge, upon trust, if a professorship of animal embryology be not in existence at his decease, or, if existing, be not adequately endowed, then for such professorship (and assistants, &c) or its further endowment, this professorship being called the "Charles Darwin" Professorship, for research and teaching in this subject from a purely scientific aspect, and subject thereto upon similar terms for a professorship of biophysics If both of these be already constituted and adequately endowed, then he left it for such purpose as may best serve the interests of biological science —By the will of the late Miss Annie Mary Fraser, of Aberdeen, the following, among other, bequests are made £3000 to the Aberdeen Royal Infirmary, £2000 to the Aberdeen Royal Hospital for Sick Children, £500 to the Morningfield Hospital, Aberdeen, £250 each to the Aberdeen Dispensary, the Aberdeen Maternity Hospital, and Aberdeen Convalescent Hospital and the residue of the property, about £30,000, for a nursing home in Aberdeen for those not able to pay the charges of ordinary nursing homes —The directors of the Prudential Assurance Company have voted a sum of £1200 for the purchase of radium to be used in the treatment of cancer at the Westminster Hospital —Miss Mary Agnes Clarke, of Morecambe, Lancs, left £1000 to the Queen Victoria Hospital, Morecambe, for a bed to be known as the "Mary Clarke" Bed —Miss Elizabeth Wills, of Crewkerne, Somerset, left £1000 to the Crewkerne Cottage Hospital —The Middlesex Hospital is to receive a sum of £10,000 from an anonymous donor, who has promised to add to this sum as circumstances permit, for the special purpose of building a new home for nurses —Miss Jane Eliza Turner, of Peckham, besides other bequests, left £1000 to St Mark's Hospital, City road, E C, £200 to the Cancer Hospital, Brompton, S W, and £500 to the Royal London Ophthalmic Hospital —Dr William John Miskelly, M D, B S, Everton, Liverpool, who left £10,070, gave the whole of his property in trust for his wife and daughter, and on the death of the survivor of them to the Royal Medical Benevolent Fund —Miss Alice Maud Ridgway, Stoneycroft, Liverpool, who left £7673, gave the residue of her estate for such hospitals or sanatoriums for the treatment of tuberculosis as the executors may select.—Dr Ernest Septimus Reynolds, M D, D L, F R C P, D Sc, of Manchester, formerly professor of clinical medicine in the University of Manchester and physician to the Royal Infirmary, left £1000 to the Manchester Royal Infirmary to endow a bed in memory of his work in that institution —Sir Frederick George Painter, of The Boltons, South Kensington, S W, left £1000 to the Bristol Infirmary for general purposes, £500 similarly to the Bristol General Hospital; £500 each to several other institutions, including the British Home and Hospital for Incurables, Streatham, the Royal Female Orphan Asylum and the Blue Maids Orphanage, Bristol, and £200 to his "valued friend and medical attendant for over 10 years," Mr Philip Birch, of Gunterstone-road West Kensington —Mr John Edward Potts, of Hampstead, gave £100 each to the Royal Chest Hospital, City-road and the Royal Northern Hospital —Major James Joicey, Poulton Priory, Fairford, Glos, left property of the value of £188,123 After certain annuities and bequests he left all his other property to his wife for life, with remainder to such charities or charitable objects as his wife may appoint

FOCAL SEPSIS IN ITS RHINOLOGICAL ASPECT.*

BY T B LAYTON, D S O, M S LOND.

SURGEON TO THE THROAT AND EAR DEPARTMENT, GUY'S HOSPITAL.

EXCLUDING direct extension through the tissues or along a surface an infection may spread by a lymphogenous or an hæmatogenous route The idea of the spread of acute disease from one site in the body to another by the blood stream has long been present in the mind of the physician It preceded the discovery of micro-organisms; it is one of the first that the student grasps on his entry into the wards He realises the danger of suppuration in a distant joint from acute osteomyelitis, whether of the temporal bone or of the head of the tibia He is on the look-out for an abscess of the liver in appendicitis or of the lungs in mastoiditis, and he calls the resulting condition " pyæmia " The idea that a chronic disease may have a similar causation is more recent, and the student meets it at a later stage. It is prominently before us at present, and is in my opinion destined to have a permanent place of growing importance among our concepts of disease This, like all new ideas, requires careful thought

Sepsis as a Cause of Chronic Disease

We mean by it that many chronic diseases are due to the constant absorption into the blood of organisms or of their toxins from some site distant from any lesions produced in the course of the chronic disease The name of ' focal sepsis " has been given to this idea, and the place in which the organisms are developing or are manufacturing their toxins is known as the " focus of infection " or the " site or source of sepsis " These organisms may be residing in this site without ever having given rise to any symptoms therein or to so few and trivial that the patient has taken no notice of them. On the other hand they may have caused one or more attacks of acute symptoms which have entirely subsided but which the patient has not connected with the chronic disease from which he is suffering It is clear that if this concept of disease be correct the right line of treatment is to stop the constant absorption of organisms or of toxins into the blood-stream by removing or otherwise dealing with the source of sepsis If we can do this we may expect, if not to cure the disease, at any rate very materially to alleviate the sufferings of the patient and to stay the further progress of the malady It is also clear that if this prove to be the correct explanation of the pathology of any given chronic disease, it may also be the explanation of any other chronic disease of unknown pathology Therefore it is right for us to investigate this latter disease along similar lines, so long as we are not doing our patients any harm thereby or subjecting them to any unnecessary risk. The situations in the body which have been found to be possible foci of infection may be put under three groups First, there is the alimentary group, which includes such sites as the gall-bladder, the appendix, or the colon as a whole; secondly, there is the genito-urinary group, which includes the glands of the prostate in the male and the cervix uteri in the female; and thirdly, the group in the upper respiratory tract which is our more immediate business

When then, we have a patient suffering from some chronic disease the pathology of which we think, might be explained on this concept of focal sepsis, we should if we were scientific, investigate all the sites in each of these three groups, we should see whether there is any disease in all or any, and whether we can cultivate a pathological organism therefrom. But in clinical medicine we can never be scientific, we can only apply the advances which science gives us to our art of healing Or put differently, the science of the clinician differs from the science of the laboratory worker and the former is most truly scientific when he realises his limitations and does not try to plan his investigations on a patient along the same lines as the laboratory worker plans experiments which are subject to controls

Thus in the hypothetical case before us the routine investigation of the first two groups is ruled out, the first by danger and by expense the second by decency. To the investigation of the third group these objections do not apply, and this may explain why, in spite of certain brilliant successes there have been many disappointments For the person who examines such a case may be a believer, who quite subconsciously sees what he wants to see or what he is asked to see, or he may be a conscientious sceptic who will not make a deduction until he has proof, who will not report definitely that there is a source of sepsis in the upper respiratory tract unless he is certain that it is there, and

---

[*] Based on a clinical lecture delivered at Guy's Hospital

Middlesex Hospital —Notwithstanding that, for reasons that are familiar, this great hospital has been working under serious difficulties, the report for 1925 is, the governors say, very satisfactory The number of patients dealt with was 5103, a slight falling off on the other hand, the out-patients, at 39,579, showed an increase of 1320 The attendances numbered nearly 197,000, a growth of more than 14,000, and it is a notable circumstance that 60,452 of these attendances were dealt with in the electro-therapeutic and massage department Each in-patient cost an average of a fraction over £13 During the year the Cancer Charity of the hospital, which is £17,000 in debt, treated 718 in-patients and 233 new out-patients Each in-patient cost £28 12*s* 11*d*

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Parliament was summoned from its holiday on Monday and Tuesday last to reconsider and renew the Emergency Regulations, in view of the coal dispute No other business was taken, but the following question of medical interest was answered

After-effects of Encephalitis Lethargica

In reply to Mr Rhys Davies, Mr Neville Chamberlain (Minister of Health), on August 31st, said that the provision of suitable accommodation for persons suffering from the after-effects of encephalitis lethargica was receiving his careful attention An experimental unit for the treatment of 100 cases had already been opened by the Metropolitan Asylums Board at Winchmore Hill A certain number of persons certified under the Lunacy Acts were suffering from the after-effects of encephalitis lethargica, and arrangements had been made by the London County Council to provide for the treatment of London cases at the West Park Mental Hospital, so that the study of the problem might be concentrated A measure had also been introduced into Parliament to amend the Mental Deficiency Act so as to facilitate the admission into mental deficiency institutions of cases suitable for treatment therein

Adami —On August 29th, J George Adami, C B E , M D , F R S , Vice-Chancellor of the University of Liverpool.

Depree.—On August 30th, Hubert Templer Depree, M.B , B Ch. Camb M R.C S Eng , L R.C P Lond., of 1, Higher Summerlands, Exeter

Fraser.—On August 19th, at Raipur India, of cholera , Lieut -Colonel W J Fraser, F R.C SE , I.M S., third son of the late John Fraser, Abbotsford, Ceylon, and Wolf Crag, Bridge of Alan, aged 45

Gasperine.—On August 13th suddenly in New York, U S.A., John Jones Gasperine, M R.C S Eng , L R.C.P Lond , D.P H , of Willoughby road, Hampstead.

Glover.—On August 25th, in Spain, of diabetes after ten years' illness heroically borne, James Glover, M.B , Ch.B , of Bentinck-street, W , aged 44

Molony —On August 20th, at Porlock, Somerset, FitzJames Molony, L.R.C P & S I , aged 68

Powell.—On August 28th, after a few hours' illness at The Firs Worcester road Sutton, Samuel Arthur Powell, O B E., M D Belf., of Harley-street, W , and late of Bombay

Price.—On August 16th, at Uppermill, David Price, M R.C S , L.R.C P

N.B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Comments, and Abstracts.

FOCAL SEPSIS IN ITS RHINOLOGICAL ASPECT *

By T B Layton, D S O . M S Lond ,

SURGEON TO THE THROAT AND EAR DEPARTMENT, GUY'S HOSPITAL

Excluding direct extension through the tissues or along a surface an infection may spread by a lymphogenous or an hæmatogenous route The idea of the spread of acute disease from one site in the body to another by the blood stream has long been present in the mind of the physician It preceded the discovery of micro-organisms , it is one of the first that the student grasps on his entry into the wards He realises the danger of suppuration in a distant joint from acute osteomyelitis, whether of the temporal bone or of the head of the tibia He is on the look-out for an abscess of the liver in appendicitis, or of the lungs in mastoiditis, and he calls the resulting condition " pyæmia " The idea that a chronic disease may have a similar causation is more recent, and the student meets it at a later stage It is prominently before us at present, and is in my opinion destined to have a permanent place of growing importance among our concepts of disease This, like all new ideas, requires careful thought

Sepsis as a Cause of Chronic Disease

We mean by it that many chronic diseases are due to the constant absorption into the blood of organisms or of their toxins from some site distant from any lesions produced in the course of the chronic disease The name of ' focal sepsis " has been given to this idea, and the place in which the organisms are developing or are manufacturing their toxins is known as the " focus of infection " or the " site or source of sepsis " These organisms may be residing in this site without ever having given rise to any symptoms therein, or to so few and trivial that the patient has taken no notice of them. On the other hand, they may have caused one or more attacks of acute symptoms which have entirely subsided, but which the patient has not connected with the chronic disease from which he is suffering It is clear that if this concept of disease be correct the right line of treatment is to stop the constant absorption of organisms or of toxins into the blood-stream by removing or otherwise dealing with the source of sepsis If we can do this we may expect, if not to cure the disease, at any rate very materially to alleviate the sufferings of the patient and to stay the further progress of the malady It is also clear that if this prove to be the correct explanation of the pathology of any given chronic disease, it may also be the explanation of any other chronic disease of unknown pathology Therefore it is right for us to investigate this latter disease along similar lines, so long as we are not doing our patients any harm thereby or subjecting them to any unnecessary risk. The situations in the body which have been found to be possible foci of infection may be put under three groups First, there is the alimentary group, which includes such sites as the gall-bladder, the appendix, or the colon as a whole , secondly, there is the genito-urinary group, which includes the glands of the prostate in the male and the cervix uteri in the female . and thirdly, the group in the upper respiratory tract which is our more immediate business

When, then, we have a patient suffering from some chronic disease the pathology of which, we think, might be explained on this concept of focal sepsis, we should, if we were scientific, investigate all the sites in each of these three groups , we should see whether there is any disease in all or any, and whether we can cultivate a pathological organism therefrom But in clinical medicine we can never be scientific , we can only apply the advances which science gives us to our art of healing Or put differently, the science of the clinician differs from the science of the laboratory worker, and the former is most truly scientific when he realises his limitations and does not try to plan his investigations on a patient along the same lines as the laboratory worker plans experiments which are subject to controls

Thus, in the hypothetical case before us, the routine investigation of the first two groups is ruled out, the first by danger and by expense, the second by decency. To the investigation of the third group these objections do not apply, and this may explain why, in spite of certain brilliant successes, there have been many disappointments For the person who examines such a case may be a believer, who quite subconsciously sees what he wants to see or what he is asked to see , or he may be a conscientious sceptic who will not make a deduction until he has proof, who will not report definitely that there is a source of sepsis in the upper respiratory tract unless he is certain that it is there, and who requires the more proof to give this report the more often he hears of its being given by other observers on what he believes to be insufficient evidence The relative ease with which the potential foci are investigated forms, then, one difference between the third and the other two groups

---

* Based on a clinical lecture delivered at Guy's Hospital.

Various Sites of Origin

The various sites in the upper respiratory tract which are or may be foci from which sepsis spreads to different parts of the body fall under three subheadings those connected with the teeth, those connected with the submucous lymphoid tissue, and those connected with the mucous membrane of the nose and its accessory sinuses It would as ill behove a rhinologist to give opinions on dental surgery as upon urinary surgery, were it not that the former is so near his own part of the body that he is bound to acquire opinions on certain points which must be considered later Of the lymphoid tissue it is the faucial tonsils with their deep crypts which form the important masses, the pharyngeal and lingual tonsils and the smaller masses of lymphoid tissue scattered about the lateral and posterior walls of the pharynx have not as yet been accused of being sites of sepsis, nor would it appear that they are likely so to become. With the nose it is different Up to now it has been the sinuses to which attention has been paid ; it may be a profitable line of investigation to consider whether the mucous membrane of the nasal fossæ proper, with the nasopharynx added, may not equally be a site from which organisms or their toxins may spread to distant parts of the body For the present, however, we may say that the two structures which have to be considered are the masses of lymphoid tissue which form the faucial tonsils and the mucous membrane lining the accessory sinuses of the nose Now both these structures have this in common—that it is a part of their function to destroy the organisms which are constantly entering the nose and mouth This paradox is therefore true that these structures are most normal when they show signs of resistance to infection—in other words, when they are inflamed In this lies the second great difference between these and the sites of sepsis in the other groups that I have mentioned If the bacteriologist can find a streptococcus in the fæces, it is probable that this organism is present in the colon to an extent which is above the normal If after massage of the prostate organisms can be found in the threads that are in the urine, it may be considered conclusive evidence that here is a potential focus of infection, and the same may be said when a pathogenic organism is cultivated from the cervical canal. But, in the present state of our knowledge, it cannot be said that the mere finding of an organism in the crypts of the tonsil before or after removal, or the mere presence of an organism in the washings from a sinus, is evidence that either of these positions is a site from which focal sepsis may arise In other words, a minor degree of infection of the tonsil or of an accessory sinus is neither a clinical nor a pathological "entity," whatever that term may mean.

Condition of the Tonsils.

In considering whether the tonsils may be a source of sepsis there is a considerable number of cases in which the rhinologist can say that there is no doubt the tonsils should be removed, whether there be some distant disease or no ; when this is done it is possible to watch the effect of their mere removal upon the course of disease and to make cultivations from them and see the effect of autogenous vaccines made from any pathogenic organism found therein When all the evidence has been obtained one may say whether the condition of the tonsils had any relation to the disease in question At the other end are a few patients in whom the rhinologist may say he does not think the tonsils can be a source of sepsis Here he can seldom speak with dogma, and, indeed, it is doubtful whether he can ever long withstand cross-examination on this point In fact, we may say without much fear of contradiction that the rhinologist can never be absolutely certain that the tonsils in any given case may not or cannot be a sourse of sepsis Between these two there lies a large number of cases, perhaps the majority, in which it is a nice point whether or no the tonsils are a source of sepsis, and where the question of removal depends upon the importance to the patient of excluding every possible site from which the sepsis may arise The decision on this point must lie with the physician He alone can weigh all the pros and cons ; he alone can weigh the likelihood of improvement of the general disease as the result of the report of the rhinologist, against the risk of the operation and in the light of other reports of other specialists who deal with different parts of the body—parts which may be, as it were, competitors with the tonsil for priority as sources of sepsis The relation of the physician to the rhinologist may be a three-fold one The former may, in the first place, instruct the latter to remove the tonsils, having made his own decision as to their condition The rhinologist is then the mere hand-worker, devoid of responsibility for the decision, except that he should give warning if he thinks the physician has not adequately estimated the risks of the operation In the second place, he may ask the rhinologist his opinion as to whether the tonsils are a source of sepsis without relation to the specific disease This is perhaps the best relationship of the three. The rhinologist will consider the condition of the tonsils and the history of any symptoms which may be referred to the throat This two-fold investigation is very necessary It is a condition in which the history, where properly obtained without suggestion and without vagueness, is almost as important as is the observation of the parts It is but seldom that the tonsils can definitely be said to be a source of sepsis unless some symptoms referred to the throat have occurred There must always be doubt in those cases in which the patient has never had a suspicion of any trouble with his throat until some general disorder has suggested the possibility of the tonsils being foci of infection Lastly, the physician may ask whether the condition of the tonsils bears any relation to the disease from which the patient suffers In this the rhinologist should be careful how he approaches the case ; it is not for him to give opinions based on general observations of disease, but only such as can be based upon such evidence that he may obtain from the case before him This evidence is limited to the association in time, of some acute infection of the throat, and either the onset or an exacerbation of the general disease. The patient may have observed that such exacerbations coincide with or follow after an acute tonsillitis or that the original onset came after a very severe or initial attack of this disease Sometimes it is possible to observe changes in the throat during such an exacerbation, though the physician usually has a greater opportunity of watching these than has the rhinologist

Sinus Infection

The problems connected with the sinuses are similar There are those cases in which suppuration in some cell is found, and the treatment of this is likely to lead to great improvement in any disease At the other end of the scale it is impossible for any rhinologist dogmatically to say that, in the case before him, there is no sinus disease Tucked away in some far distant cell may be a bead of pus which gives no evidence within the nose either by anterior or posterior rhinoscopy Perhaps it is this impossibility of giving a negative opinion that causes a positive one to be made so often The extent to which investigations should be made to find such a possible bead of pus is again a matter for the physician to decide The puncture of the antrum is an easy operation, relatively devoid of danger, which yields results that are generally trustworthy Not so the similar exploration of the sphenoidal or posterior ethmoidal cells ; the results obtained from the washings are much less reliable , less easy and certainly not devoid of danger ; sometimes even the cannula cannot be passed without a preliminary operation to relieve some obstruction at the front end of the nose, as when a deviation of the septum blocks the whole nasal fossa How far the rhinologist should go in such an investigation must be a matter for the physician It seems to be quite wrong to do so in any and every case where the disease has gone so far that much relief cannot be expected, or where the nasal examination reveals so healthy a mucous membrane that the chances of finding sepsis are minimal Where the disease is in some early state, where if not checked it will cripple some young person, or spoil some vigorous life, almost any line of investigation may be justified The physician alone can decide when he has received the rhinologist's report

Short of suppuration there may be inflammation in the sinuses, and this brings us to a most difficult problem. difficult to diagnose when the mucous membrane of a sinus is so inflamed, and to decide whether such a minor inflammation may act as a source of sepsis causing some distant lesion In the present state of our knowledge, it would seem that we must observe the utmost caution in any such case We must bear in mind the possibility of such a condition being present and acting as a source of sepsis, but we must not open every sinus from which a few organisms and pus cells may be extracted.

Dental Sources.

The dental diseases which are said to act as sources of sepsis are periodontitis, apical suppuration, and general caries of the teeth There is no doubt that the last should always have attention paid to it before anything else is done It is remarkable that physicians seem to look upon this as the least likely of the three to be the cause of focal sepsis ; they have even been known to send to the rhinologist for report patients with mouths full of broken off stumps and of molars with large cavities The other two, again, are diseases about the presence of which there may be room for great differences of opinion among dental surgeons In deciding whether the tonsils should be first removed or the mouth made edentulous the former may well claim priority, unless the evidence in favour of the latter is overwhelming

It is a great loss for a patient to have every tooth removed, especially a woman approaching middle age There is many a one who has been changed from youth to old age in a few days by the loss of all her teeth Further, the very plates the dentist makes may themselves act as a source of sepsis as much as the teeth he has previously removed I am not yet sure that this is so, but I shrewdly suspect it, and I ask you to follow up this train of thought and see whether you can get any evidence on the point

---

HELIOTHERAPY NATURAL *VERSUS* ARTIFICIAL.

To the Editor of THE LANCET

SIR,—In your review on July 10th of Dr Saidman's book, "Les Rayons Ultra-Violets en Therapeutique," the following passage occurs —

> "We think it unfortunate that the author pins his faith so exclusively upon a photo electric explanation of all the complex effects in living things which follow upon ultra violet exposure No doubt it plays some part in some of the processes, but there is so little direct experimental work in support of the theory that it would seem better to keep an open mind on the subject, rather than to reject summarily other facts which may bear upon the vital processes which are quickened so amazingly by judicious exposure to the rays "

I wish to confirm the reviewer's opinion from considerable personal experience

Heliotherapy was well known to the ancients, but when science discovered the curative properties due to the ultra-violet or invisible actinic rays outside the solar spectrum, medical attention turned to devising apparatus by which those rays could be produced artificially whenever and wherever required Thus were brought about the quartz lamp and other electrical devices which generate ultra-violet rays, and these have been used with marked success in urban communities where the upper atmosphere is nearly always laden with soot and other impurities, or where the geographical position and general physical conditions tend to the frequent occurrence of fog, cloud, and lack of sunshine

At first it was considered possible that exposure of the body, either wholly or in part, to artificial sunlight would be as efficacious as exposure to the sun itself, but this is now proved by actual experience to be an error Natural heliotherapy possesses further advantages derived from climate and locality, whether on the seashore or in the higher altitudes of the Alps This can be partially explained by the inability to reproduce in our hospitals, nursing homes, and sanatoria the scenic surroundings, the exhilarating effects of the pure and bracing atmosphere, and the results of solar radiation due to reflection from the immense mirror of the sea or from the snow fields in the mountains This is not to say that heliotherapy cannot be used with great advantage where the atmospheric and climatic conditions are less favourable, as will be realised by all who have read the recent note on heliotherapy in pulmonary tuberculosis, published in THE LANCET by Dr Wood, the medical superintendent of the Sanatorium for Sailors at Liphook

It is to the phenomenon of reflection and consequent multiplication of the actinic rays that Prof Gioseffi and other specialists attribute the rapid curative power of natural heliotherapy in the case of children and young people suffering from anæmia, rickets, enlarged glands, and naso-pharyngeal trouble, where the treatment by artificial heliotherapy is tedious and uncertain The success of the treatment of surgical tuberculosis by exposure to the sun combined with sea-bathing, was well illustrated in the columns of THE LANCET in an article by Mr Battle describing the treatment at Dr Pascal's institution of Santa Maria, Cannes For lupus and other skin diseases, where the general health of the patient is otherwise good, the artificial treatment has the advantages that the rays can be restricted to the affected part and the patient can be cared for in strict privacy, but in many other circumstances, and especially where there is mental depression, treatment by natural heliotherapy, particularly in a special home, affords that most useful adjunct, the involuntary suggestion of the other patients My experience at the Villa Iris, Alassio, confirmed by sojourn in other heliotherapeutic institutions, convinces me how much the general environment conduces to the betterment of many classes of patients, especially those of the neurasthenic type

Such patients on their arrival at the home are inclined to keep to their own rooms and when out of doors to sit alone or wander about by themselves This is encouraged here for the first few days and the newcomers are not asked to do anything except to take their sunbaths and to rest during prescribed hours Rested and soothed they gradually become aware—at first subconsciously, but in a few days consciously—of the happiness of their fellow patients They notice their merriment when going into the sea or basking in the sun in bright bathing costumes until it is time for another bathe After a few days the depressed subjects begin to think that life is worth living and gradually they mix with the other patients, enter into their interests, and take part in games At the end of the first fortnight they feel the improvement in both mental and physical condition following on the exposure to the sun and air, the sea bathing, the mental diversion, the prescribed periods of rest, and the suitable food, and from this point the progress should be satisfactory.

At Alassio, on the Italian Riviera, the temperature of the Mediterranean varies from 70° to 78°F during the months of July, August, and September, and it is no uncommon thing for people to bathe four and five times a day Nor are the summer months unendurable on account of the heat. At Alassio, speaking from personal experience, although the temperature is high it is always tempered by breezes, and the atmosphere is dry so that the heat is never oppressive This fact should be more widely known. The "sabbiatura," or hot sand bath, we have found is most valuable for the treatment of muscular rheumatism, neuritis, synovitis, and forms of osteo-arthritis Finsen said : "Nothing can replace the light of the sun which is the only, the indispensable, the irreplaceable source of vital energy "

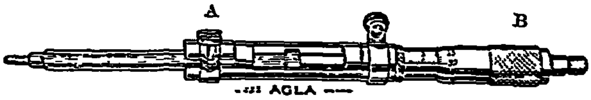
I am, Sir, yours faithfully,

F. ALEX BARTON

Villa Iris, Alassio, Italy, August 20th 1926

THE "AGLA" MICROMETER SYRINGE APPARATUS

THE accurate instrument for the measurement of extremely minute quantities of liquids, described by Dr J W Trevan in the *Biochemical Journal* (vol xix , No 6, pp 1111), is now obtainable from Burroughs Wellcome and Co It is known as the "Agla" Micrometer Syringe Apparatus and is suitable for the measurement of volumes from 0 5 c cm (with an error of less than ±0 1 per cent) to those as small as 0 001 c cm (with an error of less than 5 per cent) In immunological work the instrument can measure volumes of the order of 0 01 c cm with an error of less than ±1 per cent In the illustration the instrument is shown assembled for use The syringe is firmly clamped at A and should be so arranged that it is not quite empty when the micrometer is screwed down to the zero mark Supplied with the apparatus is a syringe of such a size that a 0 5 mm movement of the piston (one turn of the micrometer head B) will eject 0 01 c cm The syringe is filled by unscrewing the micrometer head and drawing up fluid by moving the piston by hand If the filled instrument is allowed to stand for any considerable length of time, evaporation will cause the liquid to retreat slightly from the end of the needle so that, after standing, the first 0 01 c cm should be rejected



The apparatus enables a fine degree of accuracy to be attained in various delicate laboratory processes such as immunological titrations with very small quantities of serum , the calibration of pipettes of small volume (for this purpose an ordinary fine hypodermic needle should be used and the required volume injected into the pipette by inserting the needle just inside the end of the capillary), microchemical titrations and micro-gas analyses, in which the instrument may be used as a burette

EVACUATION OF WOUNDED BY AIR

IN the French Army 3000 wounded men have been evacuated by aeroplane during the last six years, and the *Archives de Medecine Militaires* proposes to issue from time to time reports upon the current methods The original idea was to make the wounded more comfortable, but that motive has dropped into the background, the main aim now being to save life by swifter transit to hospital A perforating wound of the abdomen must be operated on within six or at most eight hours if it is to recover, and the best treatment for other wounds is primary suture, quite likely to succeed if done within six hours with gradually lessening hope to the forty-eighth hour, after which it will do no good Then, too, the dangerously wounded with fractures of thigh, spine, or skull should be taken at once to base hospitals The great difficulty of aerial evacuation is the want of landing grounds near to the fighting line and near to the hospital Some earth travel is unavoidable on each side of the air trip but it must be shortened as much as possible The general service French air-ambulance is the Breguet limousine, which carries two patients lying and one sitting, weighs two tons loaded, and travels at 100 miles per hour, but that requires a landing ground of 660 yards square, not so easy to find, especially at the front Another type of air ambulance has now been put in service, the Hanriot HD 14, which carries only one lying case, weighs three-quarters of a ton, has a speed of but 70 miles per hour, and requires a much smaller landing area. These gave satisfaction in Morocco last year as they could go up close to the front line. They work together in pairs, pick up each one wounded man, and take him back to an arranged landing place where their loads are transferred to a waiting *Breguet*, and then return to the front for more There were 26 of them in Morocco, and 10 are promised for Syria They are considered to give the best results that can be expected until the helicopter is further developed

PUBLIC HEALTH IN NORTHERN RHODESIA

A REPORT on the affairs of this Protectorate for the year 1924–25, signed by Mr Richard Goode, the chief secretary, has been issued by the Colonial Office In this it is stated that there has never been a complete census of all persons in the protectorate, but that the figures relating to the European population are known, whilst a fairly accurate estimate of the native population may be obtained from the native tax returns By this means it is computed that the native population numbers rather more than 1,100,000 No figures to show the birth- and death-rates among natives, or their immigration and emigration, are available The European population on April 1st, 1924, numbered 4182, of whom 1919 were adult males and 1016 adult females During the year 107 births and 40 deaths occurred The Asiatic population is estimated to be approximately 60, and the number of "coloured" persons about 150 The total of immigrants, exclusive of natives, was 438, of whom 407 were British subjects, 15 were American, and 16 belonged to other nationalities

The Government maintains European hospitals at Livingstone, Broken Hill, Lusaka, Mongu, Fort Jameson, and Kasama Native hospitals are also maintained at these places and at Magabuka, Fort Rosebery, and Ndola During the year 495 Europeans were admitted to hospitals, and of these nine died No figures as to the number of Europeans treated outside the hospitals are available The total number of deaths among Europeans was 40, of these 8 were due to blackwater fever, 2 to malaria, 2 to enteric, 1 to dysentery, and the remainder to various non-climatic diseases, besides 1 from accident, 1 from suicide, and 3 from premature birth In the same period 5887 natives were treated as in-patients and 49,575 as out-patients Among these there were 368 deaths Amongst the natives influenza accounted for 1500 cases, of which 74 died, 1183 of these cases and 51 of the deaths occurred at Broken Hill

The Incidence of Disease

Syphilis is widely distributed, but it has not been found possible to do more than provide treatment for those who make application for it, and they are few Similarly, the spread of tropical ulceration is due largely to the return to their homes from places of employment of untreated or incompletely treated natives, who will rarely consent to the rather lengthy treatment necessary for a cure Leprosy cases reported numbered 2789, an increase of 120 on the total reported in the previous year, but it is doubtful if these figures show the full extent of the disease No compulsory segregation has been attempted, such a policy could only be made effective by stringent regulations, backed by a larger expenditure of money than can at present be made available Most satisfactory results in the treatment of yaws have been obtained from the use of bismuth and sodium tartrate This treatment was actively carried out in the districts on the Congo border where the disease is most prevalent Arrangements have been made to provide treatment for the old or infirm who are unable to travel to a hospital to get it

Small-pox, originating in Angola, appeared in the Balovale sub-district of Barotseland in August and spread to two neighbouring sub-districts, 128 cases and 27 deaths being reported By stringent preventive measures the outbreak was soon controlled Another outbreak, introduced from the Belgian Congo, occurred in the Kasempa and Mweru-Luapula districts, but it was also kept under control Altogether, in the whole territory, 201,366 persons were vaccinated in the course of the year

Sleeping sickness and the existence of tsetse-fly continue to provide a problem, the solution of which is of vital importance to large areas of the territory Nevertheless, during the year, investigation into the disease could be carried on in only one area, that of the Luangwa Valley, where Dr. Kinghorn was at work That part of the valley which was the subject of this year's investigation stretches from Fundu at the southern end for a distance of 400 miles, in a north-westerly direction to where the Wira River joins the main stream, and as the valley may be said to average 30 miles in breadth, comprises an area of some 20,000 square miles The mean altitude is about 2300 feet above sea-level, and the climate is more tropical than most of the rest of the territory Dr Kinghorn found that an exceptionally large proportion of waterbuck and bush-buck were infected with *Trypanosoma rhodesiense* and noted that waterbuck were extremely plentiful in the vicinity of certain villages which had suffered severely from sleeping sickness He lays stress, however, on the fact that the infection has never assumed epidemic proportions The oldest natives stated that they had known the disease all their lives, and such evidence as is available tends to corroborate this Their testimony also agrees with the results of this and previous investigations to the effect that the disease appears in an extraordinarily sporadic manner, that cases are widely scattered, and that its incidence is small Dr Kinghorn's conclusions support the theory that the trypanosoma is essentially a parasite of game, and that man is ordinarily resistant to infection There is no evidence, however, to show that he acquires any immunity from it Limited resettlement was permitted during the year in the de-populated areas on the shore of Lake Tanganyika, but, though *Glossina palpalis* is still abundant there, no case of sleeping sickness has been reported It is difficult to account for this, but the suggestion has been made purely as a conjecture, that the trypanosomes may possibly have died out during the intervening years

PROGRESS IN FIJI

In his report for 1924 the Hon D R Stewart, Acting Colonial Secretary, mentions that, historically, the most important feature of the year was the celebration at Levuka, on Oct 10th, of Fiji's jubilee as a Crown colony Fifty years have brought about a vast change in the constitution of the colony's population, which at the time of cession consisted almost entirely of aboriginal natives and some 2000 Europeans and other whites The native population at the present time, while being still the largest section of the community, numbers only approximately 20,000 more than the total Indian population, and, notwithstanding repatriation, less than three times the number of Indians born in the colony since immigration first commenced in 1879 The total population, according to the 1921 census, was 157,266 (84 475 native Fijians, 60,634 Indians, 3878 Europeans, and some Polynesians and others) The health of the colony during 1924 was satisfactory There were very few cases of dysentery, and, apart from a localised epidemic at Nadi, very little typhoid fever In the later months of the year influenza was prevalent throughout the colony, it was of a mild type Infantile mortality, which is satisfactorily low among other races in the colony, is still too high among Fijians The campaign against ankylostomiasis was continued during the year, and nine-tenths of the population have now received treatment Marked improvement in general health has resulted. Examination shows that after the second treatment the number cured is 73 per cent and that the infection remaining is slight The Colonial War Memorial Hospital of 113 beds at Suva and the Lautoka Hospital of 40 beds for East Indians, serving a population of 35,000, are now completed Over 5000 Fijians received salvarsan treatment for yaws. Fourteen lepers were discharged from Makogai Asylum, as all signs of active disease had been absent in each case for over two years The births during the year were Europeans, 136, Fijians, 3015, Indians, 2280, and others, 139 The deaths were Europeans, 42, Fijians, 1080, Indians, 325, and others, 42 The vaccination of native children was continued, over 1400 being inoculated in the course of 1924 The Indian population, which has now increased to 65,000, is for the most part resident in Suva and the sugar centres of the colony, it is in the main an agricultural population, though the numbers of Indians who are engaged in commercial pursuits tend to increase annually The progress of the Fijian native has been considerable during the last 50 years. The mean shade temperatures at Suva for the year were 71 3° minimum and 82 4° F maximum, and the total rainfall at the same place was 108 80 inches

THE EFFECT OF ZINC ABSORPTION UPON HEALTH.

ZINC is so commonly associated with lead, arsenic, and cadmium that symptoms among workers where zinc ores are smelted and refined, and zinc products are made, may possibly be due to other substances In the August number of *Industrial Hygiene* R P Batchelor, J W Fehnel, R M Thomson, and K R Drinker discuss cases reported by others from this viewpoint, and find them wanting A crucial test is then described in detail wherein 24 workmen who, over a period of years from 2 to 35 had been regularly exposed in atmospheres dusty with metallic zinc, zinc oxide, and zinc sulphide, were placed under observation in hospital and thoroughly overhauled The interest in the test centred on the fact that the ore, Franklinite, from which the various dusts originated contained only minute and negligible traces of lead, cadmium, or arsenic Three case-reports are given in detail, in addition to past history each system of the body was examined intensively, including radiography of the chest Nothing abnormal could be detected, even though the zinc content of the blood per 100 c cm was 0 153 mg as against 0 387 for controls and of the urine was 1 06 mg as against 0 80, while zinc in 24 hour fæces was 10 77 mg as against 0 32 The evidence is clear that abnormal amounts of zinc may enter and leave the body for years without causing symptoms detectable clinically or by laboratory examinations

Cameron Prize Lectures

ON

SOME RESULTS OF STUDIES IN THE PHYSIOLOGY OF POSTURE

Delivered at the University of Edinburgh, May 19th and 20th, 1926,

BY RUDOLPH MAGNUS,
PROFESSOR OF PHARMACOLOGY, UNIVERSITY OF UTRECHT

PART I

THE study of the physiology of movement is of old origin Movement affords many points of attack for research because by movement changes in the condition of the body or its parts occur, which attract the attention of the observer and can be recorded and measured This is not the case when posture is studied Here we have to deal with a constant condition without apparent changes so that our desire for causality is not stimulated, and we therefore do not immediately suppose that active processes are at work In consequence of this the physiology of posture is of relatively recent date and many facts to be described in these lectures have been discovered by still living physiologists during the last 40 years, among whom Sherrington must be named in the first place The chief result of these investigations is that posture is an active process, and is the result of the cooperation of a great number of reflexes, many of which have a tonic character Many parts of the central nervous system contribute to the function of posture, the importance of the spinal cord and the brain-stem we understand up to a certain limit, whereas the activities of other parts, especially of the cerebellum and basal ganglia, are still obscure

For the purpose of these lectures I class postural activities under the following headings —

1 *Local static reactions*, in which only one part of the body—e g , one limb—is concerned

2 *Segmental static reactions*, which involve one segment of the body—e g , both hind-limbs, both fore-limbs, or the neck

3 *General static reactions*, in which more than one segment or even the whole body comes into action

The aspects of these general static reactions vary considerably in accordance with the part of the central nervous system which governs in different experiments the posture involved We can thus distinguish (*a*) static reactions of the oblongata animal (decerebrate preparation), in which the spinal cord is in functional connexion with the medulla oblongata only, (*b*) static reactions of the mid-brain and thalamus animal, in which in addition to the bulb the mid-brain centres also take an active part, (*c*) static reactions of the intact animal, in which the cortical centres cooperate

The importance of the cerebellum and of the basal ganglia will not be discussed in these lectures.

LOCAL STATIC REACTIONS

The limbs of mammals, as of other vertebrates are built up of bony segments, linked by a complicated arrangement of ligaments and moved and fixed by muscles, fasciæ also play a role The whole system is easily movable in different directions Our problem is to explain how such a movable limb is at times used as an *instrument* for very different purposes (such as scraping, scratching, fighting &c) and moved freely in all joints, whereas at other times it is transformed into a stiff and strong *pillar*, which gives the impression of being one solid column, able to carry the weight of the body Experiments have shown that this is accomplished by a series of local static reflexes

We were confronted in the laboratory with this problem during the investigation of decerebellated animals, which had been operated upon by Dr. G G J Rademaker, and of which the condition of muscle-tone had to be followed during the course of many months It soon became evident that this was not a simple task, and that the state of tone of a limb at any given moment depended greatly upon the way in which the tone is investigated If, for instance, a dog is lying down in the lateral position and the resistance of one fore-limb against passive flexion is measured with the hand and fingers flexed, often no resistance can be felt But if the latter are extended and pressure exerted against the pads of the foot, then the fore-limbs become strongly extended and can hardly be flexed at all The same difference can also be demonstrated in intact animals We therefore decided to make a more detailed investigation of these reactions In addition to Dr. Rademaker, Dr R Schoen (Würzburg) and Dr E A Blake Pritchard (London) took part in this research, Dr Schoen experimenting on the general conditions for these reflexes and on a graphical analysis of the muscles of the fore-limbs, while Dr Pritchard investigated the hind-limb in the same way

The best way to evoke this static reflex is to press against the pads of fingers or toes and to dorsiflex the hand or the foot Then the limb becomes more or less stiff, and is, in the prone position of the animal, able to carry the weight of the body

Two different stimuli cooperate in evoking this reflex

1 The *proprioceptive* stimulus evoked by the dorsiflexion of the distal parts of the limbs (fingers and hand, toes and foot) These proprioceptive influences can be isolated by cutting the local sensory nerves for the skin of hand and foot They disappear after cutting the tendons of all plantar or volar flexor muscles to the distal part of the limb

2 The *exteroceptive* stimulus evoked by the contact of the pads of the feet with the ground If a decerebellated dog be placed in the supine position with the head ventroflexed by 90°, then the hind-limbs are usually flexed in all joints A very slight touch to the pads of the foot is sufficient to evoke a strong tonic extension of the whole hind-limb, even if dorsiflexion of foot or toes is carefuly avoided by keeping the fingers only just in contact with the foot It appears as though the slowly extended foot were being drawn after the receding finger by some magnetic force The reflex has therefore been called the "magnet reaction" As soon as the finger is removed, the limb goes back into flexion The exteroceptive stimulus can be isolated by cutting all the tendons to the foot or hand and disappears only after severing the sensory cutaneous nerves to the foot

The static response ends and the whole limb is loosened and becomes free for movement by the removal of the two above-named stimuli, which takes place as soon as the limb in the standing animal is lifted from the ground, but, as is usual in very important functions, an active process cooperates As soon as the distal part of the limb is flexed in the volar or plantar direction, the limb is reflexly loosened and prepared for movement

We call the whole process the *supporting reaction* The passing from the flexible condition to the stiffness of a support is called the *positive supporting reaction*, whereas the loosening of the limb is called the *negative supporting reaction*

A *The Positive Supporting Reaction*

This reflex can be studied in the intact animal as well as after extirpation of the whole cerebrum or cerebellum It is also present in certain stages of general narcosis The following description is based especially upon the findings in the fore-limbs of cats The results on the hind-limbs will only be mentioned if necessary The effective stimulus for this reflex is stretching of the flexor muscles of fingers and hand The deep flexor muscle of the fingers alone is sufficient to evoke the reflex But also other flexor muscles can serve this purpose The exteroceptive stimuli from the pads of the toes coöperate to the same effect

1. The *anatomical arrangement* plays only a rôle of secondary importance for the establishment of the supporting reaction Formerly there was a general belief in the importance of the ligaments for the fixation of the joints, but at present there is a tendency to believe that the tonic activity of muscles is the most important factor

That the arrangement of ligaments cannot explain the supporting reflex follows from the fact that in cats and dogs during ordinary standing all three main joints of the hind-limbs are semiflexed, and can be moved from the resting position in both directions Also in man in easy standing the ligaments of the leg are only of secondary importance. The muscles have the function of supporting each part of the limb and the body as a whole For that purpose they are brought into tonic contraction by impulses from the central nervous system The supporting reaction is reflex This is already proved by the fact that simple pressure against the pads of the foot is sometimes sufficient to evoke the reflex by exteroceptive stimulation The following observations point in the same direction

In the first hours after extirpation of the fore-brain the supporting reaction is absent in spite of the presence of sufficient muscle tone The post-operative shock has suppressed the reflex in an animal, which can right itself and even walk Several weeks or months after severing the posterior roots to a fore- or hind-limb the movements are fairly well restored, and it is possible, by changing the position of the head, to increase the tone of the desensitised limb , in spite of this no trace of a supporting reaction can be felt. In deep narcosis it is impossible, by changing the position of its most distal part, to transform the limb into a supporting pillar

All these facts show that the anatomical arrangement alone, even if the muscles have some tone, cannot explain the supporting reaction

One arrangement deserves special attention the two-joint muscles A part of the flexors of hand and fingers stretched during standing takes its origin from the medial epicondyle of the humerus, and can extend the elbow In doing this the biceps is stretched and, if this muscle comes into tonic contraction, it can extend the shoulder, which in turn stretches the caput longum of the triceps, so that contraction of this muscle can extend the elbow Simultaneous contraction of biceps and triceps fixes not only the elbow, but also the shoulder In the completely relaxed limb under deep narcosis or immediately after death this mechanism does not act, only extension of the elbow can be evoked by extension of the shoulder , but in the normal animal or when, after death, the muscles become rigid from rigor mortis, the two-joint muscles exert their influence For this effect therefore reflex tension of the muscles is a necessary condition

From the foregoing remarks it follows that the anatomical arrangement by itself cannot explain the supporting reaction, but constitutes the mechanism through which the physiological processes can play their rôle

2. Of great importance are the *myotatic reflexes* of Liddell and Sherrington These authors found in decerebrate preparations tonic reflex contractions caused especially in the extensor muscles by even slight stretch of the muscle The increase of tension is confined to the muscle, which is stretched, and even one part of a muscle can show this purely proprioceptive reflex, if this part only is subjected to stretch According to Forbes, Cobb, Fulton and Liddell, contraction may be confined to only a part of all the fibres of a muscle, just sufficient in number to counterbalance the stretch, or to carry the weight which causes the increase of tension If these muscle-fibres become fatigued, other fibres go into contraction, and alternation of the active fibres makes it possible for the muscle as a whole to be indefatigable during myotatic activity The reflex begins with a stretch and an increase of tension, and continues as maintained tension at a constant, increased length The weight being thus just counterbalanced by the particular muscle-fibres in action at the moment, the others are prepared to move the limb or body, just as smoothly as if no weight at all was present.

This myotatic reflex comes into play in the flexor muscles of hand and fingers, which are stretched during standing by the dorsiflexion of these parts of the limb, and therefore react by increase of tension In other muscles of the limb also, especially in the extensors of elbow and shoulder, if they become stretched during static activity, myotatic reflexes may coöperate with the direct supporting reflexes

But besides these myotatic reactions many other reflexes cooperate in the supporting function

3 According to Liddell and Sherrington, the myotatic reflexes in the decerebrate preparation are limited to the stretched muscles, or parts of muscles This is not the case with the supporting reaction in normal or thalamus animals If in experiments with graphic registration one or other flexor tendon to the hand or to one or more fingers is severed from its insertion and connected with a recording lever, it is seen to contract, although not stretched, when the hand and toes are dorsiflexed In the course of the experiments the contraction of all the different flexor muscles during the static reflex has been in turn recorded These facts show that the extension of the flexor muscles during standing sets up reflexes, which tend to bring into play the whole group of flexor muscles on the fore-arm, and that we have to deal with synergistic reinforcement of tonic contraction

4 How do the *extensor muscles* react in the positive supporting reaction ? They are not stretched at all In a long series of marvellous investigations it has been shown by Sherrington that in ordinary *movements* antagonistic muscles obey the law of reciprocal innervation Also in the experiments of Schoen reflex flexion of the hand was accomplished by contraction of the flexors and simultaneous relaxation of the extensors ; and reflex extension of the hand (e g , in the crossed extension reflex) by contraction of the extensors with relaxation of the flexors But as soon as the supporting reflex was evoked by pressure against the pads of the sole and by dorsiflexion of hand and fingers, then there was a simultaneous contraction of both flexors and extensors The functional grouping of the antagonistic muscles differs totally in the supporting reflex from that in ordinary movements the antagonistic muscles exert a synergistic function and the result is *fixation of the joint*

5 The elbow also becomes fixed

(*a*) The fixation against flexion is accomplished by mechanisms differing according to the various possible positions of the fore-limb *In the first place*, as mentioned above, the flexors of fingers and hand, especially the flexor digitorum profundus, take their origin from the epicondylus medialis humeri, and will therefore, if stretched during standing, cause fixation of the elbow directly by myotatic reflexes *In the second place* dorsiflexion of hand and fingers gives rise to reflex contraction of the triceps *In the third place*, stretch of the triceps evokes a myotatic reflex upon this muscle, and finally, if in the supporting reflex the biceps is stretched (by flexion of the shoulder) this also gives rise to a reflex contraction of the triceps

(*b*) The fixation against extension is secured by a reflex contraction of the biceps caused by the dorsiflexion of hand and fingers, reinforced by a reflex, taking its origin in the stretched triceps

All these *different* reflexes cooperate, reinforce, and, if necessary, replace each other, so that standing under very different positions of the joints becomes possible

6 The fixation of the elbow, as *far* as the biceps and the long head of the triceps are concerned, depends

also upon the position and fixation of the shoulder-joint, as described above The shoulder is fixed in the first place by these two double-joint muscles and in the second place by the shoulder musculature itself For this joint also simultaneous contraction of flexors and extensors has been demonstrated It may be mentioned that in the experiments of Schoen the supraspinatus muscle was very sensitive to the exteroceptive stimulus of touching the pads of the fingers

7 The whole mechanism of fixation in the hand, elbow, and shoulder-joints would not be of any value for standing if there were not also a strong muscular fixation of the scapula to the thorax. The strong and broad mass of the levator scapulæ and the serratus, which are inserted on the scapula and take their origin from the neck region and the lateral parts of the thorax, form on both sides a bearing girth, by which the forepart of the body is slung between the two supporting pillars The rhomboidei, connecting the vertebral column with both scapulæ, hold these bones in position and make the bearing function of the levator scapulæ and serratus effective At the same time the pectoralis muscle and the latissimus dorsi fix the humerus to the trunk and secure the two pillars against abduction If under certain conditions the levator scapulæ and serratus should give way, the pectoralis and latissimus on both sides can form a second bearing girth, which can also carry the thorax

If the thalamus animal is hanging prone in the air, these shoulder muscles are usually tonically contracted Standing on the ground increases this tone by reflexes evoked by dorsiflexion of the toes and exteroceptive stimuli of the finger-pads

This short review, which naturally must be very incomplete, is sufficient to show how complicated is the system of different reflexes, which makes it possible to stiffen one limb and to transform it into a supporting pillar

B *The Negative Supporting Reaction*

Besides the disappearance of those conditions which evoke the positive supporting reaction active processes take an important part in interrupting the positive reaction and inducing the negative phase The active stimulus is not exteroceptive The limb in the negative phase is usually removed from the ground The volar flexion of fingers and hand in the fore-limbs or plantar flexion of the toes in the hind-limbs is the effective stimulus The reflex disappears in the fore-limbs after cutting all tendons of the extensor muscles of hand and fingers In the intact limb it is evoked by stretching these extensors In consequence of this there is a reflex relaxation of the extensor muscles of the proximal joints, which has been demonstrated by Schoen in the case of triceps, serratus anterior, and levator scapulæ At the same time the flexors of the shoulder contract The relaxation of serratus and levator scapulæ can be seen also to follow flexion of the elbow or even of the shoulder

In this way the whole limb, especially the shoulder, is loosened and becomes free for movements

The foregoing description shows the importance of local static reactions

SEGMENTAL STATIC REACTIONS

It will be sufficient to illustrate the segmental static reactions by some examples only A very simple instance is given by the crossed extension reflex. In the standing animal the weight of the hind part of the body is carried by both hind-limbs and the weight of the fore part of the body by both fore-limbs A painful stimulus applied to one limb evokes the ipsi-lateral flexion reflex, by which the stimulated foot is removed from the neighbourhood of the stimulus. The crossed limb, therefore, has to carry the weight of the fore or hind part of the body alone This is made possible by the increased supporting reactions as described above, but is aided by the crossed extension reflex, which causes increased tone in the extensor muscles of the limb

Another instance of segmental static reactions is afforded by the so-called "Schunkelreflex,"' which can easily be demonstrated in the fore- or hind-limbs of normal animals as well as after extirpation of the cerebellum or the fore-brain Suppose that the animal (dog or cat) is standing on the table and one—e g , the right—fore-limb is lifted up by the negative supporting reaction The extensor tone of this limb is continuously tested by slight passive flexions of the elbow The hand of the observer moves the thorax of the animal towards the right; then one feels an increased extensor tone of the elbow, and finally the limb is completely extended and able to prevent the fore part of the body from falling towards that side The same reflex can be demonstrated in the hind-limbs and is also present in man, especially when we are standing on one foot and move towards the other side Then the extension of the crossed knee is inevitable, and gives the subjective impression of being at least partly voluntary But in animals the reflex is very active after complete extirpation of the cortex cerebri

The reflex is not evoked by changes in the position of the head, neck, and vertebral column The stimuli arise in the main from the adductor muscles, which are stretched by moving the body in the lateral direction The reacting limb can be completely desensitised by cutting all the posterior roots carrying impulses from this limb , desensitisation of the standing limb, on the other hand, abolishes the reflex

A similar reflex is present if the body be moved forwards or backwards After lifting up one fore-limb the forward movement of the thorax causes the limb, which has been lifted up, to be extended and moved forwards, so that it prevents the body from falling

The static "meaning" of this latter reaction is evident, but besides that the reaction also comes into play during walking and running This shows that the same reflex can be used for the maintenance of equilibrium and for the purpose of walking

These and other segmental static reactions, in which stimulus and effect are not confined to the same limb but to the same segment, show the interconnexion of separate parts of the body in static functions

GENERAL STATIC REACTIONS

In general static reactions more than one segment of the body, even the whole body, is concerned Many examples will be given in the course of these lectures A fundamental condition for every static reaction is that the animal shall stand or at least be able to stand In the preceding section this was supposed to be the case At the present moment we have to answer the question Which parts of the central nervous system must be present for standing ?

The classical experiments of Goltz and Sherrington have demonstrated that a *spinal animal* can perform very complicated movements If in a dog the spinal cord be divided in the thoracic region, after some months a great number of reflexes can be evoked in the limbs ipsi-lateral flexion and extension reflexes, a crossed extension reflex, rhythmic movements resembling walking and running or galloping, the scratch reflex, movements of hind-limbs and tail exactly similar to those which normal animals perform during defæcation and micturition Under certain conditions even a flexor tone of long duration may be present in such a limb—e g , when an ulcer on the foot develops; but in spite of all these very complicated and adapted innervations, no static tone is present and the limbs cannot carry the weight of the hind part of the body they give way after a very short time The same is true for a spinal animal in which the cervical cord has been cut All four limbs are under these conditions deprived of static tone

In the "decerebrate" preparation the state of affairs is quite different In these animals the brain-stem has been cut across somewhere between the plane of entrance of the eighth nerves and the foremost part of the mid-brain It has been shown by Sherrington that after decerebration the “ decerebrate rigidity ” develops, which is characterised by a strong tonic contraction of the “ antigravity ” muscles—viz , the extensors of the limbs and back, the elevators of neck and tail, and the closing muscles of the jaw The antagonists of these static muscles, the flexors, have either a very slight tone or even none at all If placed on its feet the decerebrate preparation will stand, that is to say, the strongly extended limbs will carry the weight of the body, but owing to the isolated and exaggerated contraction of the extensors the posture of the animal becomes abnormal and is deprived of the smoothness which is seen in intact animals Sherrington has shown that “ decerebrate rigidity ” is a reflex phenomenon The chief stimuli arise in the proprioceptive sense organs of the contracted muscles themselves Later experiments have shown that, besides this, other sensory stimuli cooperate, arising from the crossed limbs, from the neck region, the labyrinths, the fifth nerves, the skin, &c After cutting the cervical posterior roots and extirpating the labyrinths the neck muscles can still develop pronounced decerebrate rigidity It is possible to provide the completely deafferented limbs of a decerebrate animal with a fair amount of tone by stimuli from other parts of the body Experiments of Bazett and Penfield have shown that after decerebration the rigidity may last for weeks

The reflex behaviour of the decerebrate animal differs from that of the spinal animal in a characteristic way Under both conditions the flexor muscles perform reflex contractions of short duration after stimulation of an appropriate afferent nerve The extensor muscles of the spinal animal also respond by short contractions In the decerebrate preparation the reflex response of the extensor muscles is prolonged, and shows sometimes very long after effects

The peculiarities of the decerebrate state will become still more evident when we later describe the different behaviour of animals with intact mid-brain

A GENERAL STATIC REACTIONS OF THE DECEREBRATE PREPARATION

The essential condition for these experiments is that the hind part of the bulb has been left in functional connexion with the spinal cord The presence or absence of the cerebellum is not essential, the presence of the oral part of the bulb, the pons, and the caudal part of the mid-brain causes the preparation to show a greater variety of reflexes, but does not contribute to the fundamental phenomenon in question

General static reactions in the decerebrate animal can most easily be induced by changing the position of the head This was discovered by chance Many years ago I prepared a decerebrate cat with cross section of the low thoracic cord, in order to study some reflex reactions of the tail muscles For this purpose I brought the animal from the lateral into the supine position and noticed to my surprise a slow but very strong “ pathetic ” extension of the fore-limbs, which disappeared when the animal was again placed upon its side Other changes of position evoked also tonic reactions of the fore-limbs Subsequent repetitions of the same experiment showed that various animals reacted differently A long experimental analysis in which I was joined by my friend and collaborator, De Kleyn, was necessary until we understood the phenomenon completely As usual the result was comparatively simple It is possible by giving to the head different positions, to change the distribution of tone in the whole body musculature, and, as far as decerebrate preparations are concerned, especially in the above-named group of antigravity muscles The most striking reactions appear in the extensors of the limbs and in the neck muscles The effects observed are the result of combined reflexes from the labyrinths and from proprioceptive neck-receptors, and as the relative strength of these two influences varies from animal to animal the different results of subsequent experiments can be understood In this way it is possible to impress upon the whole body different adapted attitudes by changing only the position of the head These reflexes therefore may be called *attitudinal reflexes*

Every change of the head implies two different factors (1) a change in the position of the head in relation to the body by which the neck-receptors are stimulated, and (2) a change of orientation of the head in space, which brings the labyrinths into play

These facts allow us to study the two sets of reflexes separately

1 *Tonic Neck Reflexes*

In order to study the tonic neck reflexes upon the limb muscles without interference with the labyrinth reflexes it is necessary to extirpate the vestibular organs This has been done by a method devised by De Kleyn without any lesion of the muscles on the basis cranii After this operation the influence exerted by changes of the position of the head become independent of the orientation of the head in space Only changes in its relation to the body cause tonic reflexes and these reflexes are now unequivocal all animals reacting in the same sense

Rotation of the head causes extension of the fore and hind-limbs, towards which the jaw is rotated (“ jaw-limbs ”), and relaxation of the limbs, towards which the vertex is rotated (“ skull-limbs ”) Inclination of the head towards one shoulder causes extension of the fore- and the hind-limbs towards which the nose is inclined (“ jaw-limbs ”) and relaxation of the limbs on the other side (“ skull-limbs ”) The general rule for rotation and inclination therefore is that the jaw-limbs are extended and the skull-limbs flexed Dorsiflexion of the head causes, in all mammals except the rabbit, extension of the fore-limbs and relaxation of the hind-limbs Ventroflexion of the head causes flexion of the fore-limbs and extension of the hind-limbs In rabbits dorsiflexion of the head causes extension of all four limbs and ventroflexion of the head causes flexion of all limbs In all mammals with the exception of the rabbit, movement of the head in different directions is followed by opposite reaction of one pair of limbs as compared with the other Relaxation of the four limbs in all mammals is given only by pressure upon the lower part of the cervical vertebral column in a ventral direction (vertebra prominens reflex)

The afferents for these reflexes (with the only exception of the vertebra prominens reflex) take their course through the three uppermost cervical posterior roots The centres of the tonic neck reflexes have been localised in the first and second cervical segments

2 *Tonic Labyrinthine Reflexes*

These reflexes can be studied separately after excluding the neck reflexes This can be done either by cutting on both sides the three first cervical posterior roots or by immobilising head, neck, and thorax by a strong plaster-jacket, so that no movements of the head in relation to the body are possible while the fore-limbs are left unrestrained and can be moved freely If such a preparation be brought into different positions in relation to space the extensor tone of all four limbs always changes in the same sense There is only one position in which the extension becomes maximal the supine position with snout about 45° above the horizontal plane The extensor tone diminishes to a relative minimum if the animal is brought into the prone position with snout about 45° below the horizontal plane The minimum and maximum positions differ therefore, by 180° In all other positions in space the extensor tone is intermediate between these two extremes These reflexes are not evoked by movement but depend upon position They are independent of angular acceleration and last as long as a certain position is kept Only such changes in the position of the head are effective as change in its angle in relation to the horizontal plane

The labyrinthine origin of these reflexes is proved by the fact that they disappear after bilateral labyrinth extirpation A delabyrinthised decerebrate cat in which the neck has been immobilised by a plaster bandage, can be brought in all possible positions in space without any changes in the tone of the limb muscles.

The tonic labyrinthine reflexes arise from the otolithic organs. In mammals it is not possible to prove this by isolated extirpation of the otolithic maculæ or of the ampullæ of the semicircular canals, for this cannot be done without opening the peri- or endo-lymphatic space and therefore definitely disturbing the vestibular function. Another method was therefore, used. Following a technique first devised by Wittmaack, guinea-pigs under ether were centrifuged for a short time at high speed. Then the otolithic membranes are detached by the action of centrifugal force, whereas the canals with ampullæ and cristæ remain intact. In each case a microscopic investigation must be made, and this must show that the ampullar nerve-endings and the canals are intact, that all four otolithic maculæ are completely deprived of their otolithic membranes, and that these four membranes can be found remote from them, inside the endolymphatic space. This last point is of importance, because it proves that the detachment of the membranes occurred intra vitam and not as a result of faulty fixation or cutting of the section for examination. Only from experiments with complete histological evidence may definite conclusions be drawn.

In such animals all labyrinthine reactions evoked by angular or rectilinear acceleration are present, but all reflexes resulting from position have disappeared including the tonic labyrinth reflexes upon the limb muscles. These reflexes therefore, depend upon the otoliths.

The position of the otoliths in relation to the skull has been carefully investigated by De Burlet and his pupils in the anatomical department of the University of Utrecht. The results of their measurements have been used for the construction of models (guinea-pigs rabbit, monkey, man).

The two maculæ utriculi are situated approximately in the same plane, which is nearly horizontal, when the animal carries its head in the normal position. The two maculæ sacculi are not at all in the same plane; they form as far as their chief portion is concerned an angle of rather less than 90° with the utricular maculæ. With normal position of the head the two maculæ sacculi face towards the lateral side.

If the head of a rabbit is brought into the maximum position for the tonic labyrinthine reflexes the saccular maculæ have no characteristic position, whereas the utricular maculæ are lying in a horizontal plane. In the maximum position, in which the extensor tone of all four limbs has reached its highest value, the otolithic membranes exert a pull on the macular epithelium. In the minimum position for the extensor tone, the maculæ stand again horizontal with the otolithic membranes pressing upon the epithelium. The conclusion is that the *tonic* labyrinthine reflexes are evoked from the utricular maculæ. This is confirmed by the *fact* that after unilateral labyrinth extirpation the maximum and minimum positions for the tonic labyrinth reflexes remain unchanged, which would be impossible if the maculæ concerned in these reflexes did not lie in the same plane.

In the position in which the extensor tone of the limbs is maximal the otoliths pull on the utricular maculæ. The conclusion that the maximum of stimulation in the macular epithelium is *induced, not by* the pressing, but by the pulling otolith is proved to be sound by observations on saccular reflexes a part of which will be mentioned later.

The centres for the *tonic* labyrinthine reflexes upon the limb muscles have their *position in the hind* part of the bulb, behind the plane of entrance of the eighth nerves.

Besides the tonic utricular reflexes on the limb muscles there are also tonic utricular reflexes on the neck muscles, which follow in general the same laws. The only difference is that every utricular macula sends impulses to the limbs of both sides and to the neck muscles of the crossed side only. As a consequence of this unilateral labyrinth extirpation is followed by no change in the tonic labyrinthine reflexes upon the limbs but evokes the well-known turning of the neck which has been described by all previous observers. This rotation and inclination of the head causes secondary tonic reflexes upon the limb muscles. The connexion of the labyrinths with the limbs is, therefore a double one (1) by tonic labyrinthine reflexes directly upon the limbs and (2) by tonic neck reflexes upon the limbs indirectly through labyrinthine influences upon the neck.

3 *Combinations of Tonic Labyrinthine and Neck Reflexes*

If both sets of reflexes are present, they cooperate so that the tone of every single muscle depends upon the algebraic sum of influences derived from proprioceptive end-organs in the neck and from the utricular maculæ. If, therefore the triceps muscle of the right elbow derives increased tone from the labyrinths and from the neck, the elbow will be strongly extended; if this muscle gets diminution of its tone from both sources the elbow will relax but if the muscle tone is increased from the labyrinths and decreased from the neck the result depends upon the relative strength of these influences. If the labyrinthine reflexes predominate the elbow will be extended, if the neck reflexes are stronger it will be flexed and if both reflexes are of the same strength the angle of the elbow will not change at all.

This cooperation gives rise to very characteristic attitudinal reactions of decerebrate animals. Place a cat in the prone position upon the table and flex the head ventrally then the labyrinths come into the minimum position and all four limbs will tend to relax. The neck influences cause relaxation of the fore-limbs and extension of the hind-limbs. Both groups of reflexes, therefore, cooperate in the fore-limbs, which show distinct relaxation, whereas the hind-limbs may not change at all because the influences from neck and labyrinths act in opposite senses. If with the prone position of the animal the head is bent dorsally the resulting removal of the labyrinths from the minimal position causes extension of all four limbs. The neck reflexes evoke extension of the fore-limbs and relaxation of the hind-limbs. The combined effect is strong extension of the fore-limbs and only slight changes in the hind-limbs. Head movements, therefore, in a ventral and dorsal direction have a very strong influence on the fore-limbs, whereas the reaction of the hind-limbs is much weaker.

Still more complicated is the effect of head rotation with the lateral position of the animal. In this case I shall describe only the effect upon the fore-limbs. If with the right lateral position of the animal the head is rotated so that the vertex is below, then the labyrinths are in maximum position which gives rise to strong extension of both fore-limbs. In respect of the neck reflexes the uppermost fore-limb is "jaw-limb" and will be extended, whereas the lowermost fore-limb is "skull-limb" and will be flexed. Both influences cooperate for the uppermost fore-limb, which is strongly extended. The behaviour of the lowermost fore-limb is different according as one or the other reflex preponderates. With stronger labyrinthine reflexes it is extended. With stronger neck reflexes it relaxes. When the strengths of both groups of reflexes are equal it remains unchanged. The reaction of the lowermost fore-limbs to rotation of the head with the lateral position of the animal affords, therefore, the possibility of determining in a given animal the relative strength of both sets of reflexes. If now with the same lateral position of the body the head be rotated with the vertex uppermost then the labyrinths come into the minimum position and both fore-limbs will tend to relax. In the upper fore-limb this relaxation is reinforced by the neck influence (skull-limb) In the lower fore-limb it is counterbalanced by the neck influence (jaw-limb) With preponderant labyrinthine influences the lower fore-limb is relaxed, with preponderant neck reflexes it is extended In every case with the right lateral position rotation of the head evokes very strong and unequivocal reactions of the left (upper) fore-limb, whereas the reactions of the right fore-limb are weaker and of indefinite direction Now, the animal is placed in the left lateral position and again the head is rotated The same rules can now be applied with this difference only, that the upper fore-limb is now the right one In this case the right fore-limb will react strongly and the left fore-limb may not move at all It becomes evident that one and the same rotation of the head causes with the right lateral position of the animal strong relaxation of the left fore-limb, and with the left lateral position strong extension of the right fore-limb This instance shows clearly that the same movement of the head in relation to the body may, with different spatial positions of the body, evoke very different reactions But in spite of these complications, which were very amazing at the time when the experiments were started, it has been possible to explain all reactions, observed in more than a hundred experiments, in which the head was moved about the three chief axes with each of the six main positions of the body in space by the combined action of utricular and neck reflexes

The attitudinal reflexes are called tonic, because they last as long as the head keeps a certain position They are practically indefatigable After unilateral labyrinth extirpation in rabbits the turning of the neck lasts until the animal dies Also the tonic neck reflexes upon the limbs evoked by this head rotation can be demonstrated as long as the animal is alive On the other hand, every change in position of the head is followed immediately by the corresponding change in the attitude of the whole body The influence of the tonic attitudinal reflexes is very strong upon the muscles of the proximal joints, shoulder and hip, elbow and knee. on the distal joints of hand, foot, toes, and fingers the action of these reflexes is much less pronounced

The mechanism as a whole acts in such a way that the head leads and the body follows The attitudes impressed upon the body by a certain head position in the decerebrate preparation closely resemble the natural attitudes shown by the intact animal during ordinary life

4 *Attitudinal Reactions in Intact Animals and in Man*

This leads to the question of the presence of attitudinal reflexes in normal animals with intact central nervous system In most mammals they are present and can easily be demonstrated In the normal rabbit dorsiflexion of the head in the sitting animal causes tonic extension of the fore-limbs, head rotation with the rabbit in the supine position evokes extension of the jaw-limbs and relaxation of the skull-limbs

It is not necessary that the head movements shall be passive The same laws hold good when the animal performs active head movements As these depend very often upon stimuli transferred to the animal by way of the distance receptors (eye, ear, nose), it is possible to impress upon the body of the animal different attitudes from distant points of the environment A cat which sees some food lying on the ground flexes the head in the ventral direction, and this causes the fore-limbs to relax so that the snout is moved towards the food, but if a piece of meat be held high up in the air the optic stimulus causes dorsiflexion of the head This evokes strong extension of the fore-limbs without marked extension of the hind-limbs The body of the animal is not only focused on the meat, but is also brought into a position which is optimum for the springing reflex, so that by a strong sudden simultaneous extension of the hind-limbs the animal can reach the meat

The activity of the vertebra prominens reflex can be watched in a cat or dog creeping into a hole In doing so, the animal brings its head close down to the ground with resulting relaxation of all four limbs so that the belly lies flat upon the floor

Many other instances of the action of attitudinal reflexes in intact animals have been observed A striking difference between the reaction of the decerebrate and the normal animal is that in the decerebrate preparation the flexor muscles, which have no tone, do not take part in the reaction or respond only very slightly In the intact animal the flexor muscles also, as will be shown later, have tone, and react to the tonic neck and labyrinthine reflexes In this they follow the law of reciprocal innervation Increase of extensor tone is associated with diminished flexor tone and vice versa In this way the attitudinal reflexes of intact animals are much smoother than the stiff and always exaggerated attitudes of the decerebrate preparation

In monkeys during their ordinary movements it is not easy to detect the presence of attitudinal reflexes, which, on the other hand, can with certainty be demonstrated in the decerebrate or narcotised animals

In man also the presence of attitudinal reflexes in ordinary life is not striking Good pictures and statues give the impression of being natural, if the body is represented according to the laws of attitudinal reflexes If these laws are not obeyed we get the impression of a dead body or of a caricature But the complexity of human movements during ordinary life usually obscures the simple attitudinal reactions In a certain percentage of babies, however, the influence of head rotation upon arms and legs can be seen

Under pathological conditions the presence of attitudinal reactions in man may become evident, especially when disease has interfered with the function of the higher parts of the brain Very diverse pathological conditions give rise to the appearance of these reflexes, which are now used by neurologists for diagnostic purposes, head rotation especially causes extension of the jaw-limbs, sometimes accompanied by relaxation of the skull-limbs In this case neck reflexes are present In a minority of cases also tonic labyrinthine reflexes have been demonstrated, in which all four limbs reacted in the same sense, and in which, precisely as in animals, a maximum and a minimum position of the head could be determined If both sets of reflexes are present their coöperation follows the same laws as in animals It has been shown by Simons and by Walshe that the direction of associated movements of paralysed limbs, evoked by active voluntary movements of non-paralysed parts of the body, can be influenced by the position of the head

The attitudinal reflexes form a group of tonic reactions, by which the whole body musculature is integrated for a combined and highly adapted function The entire body follows the direction assumed by the head, this being very often moved in a certain direction under the influence of the telereceptive higher sense-organs This provides one of the ways in which the relation of the body to its environment is regulated It need only briefly be mentioned that the different attitudes, with their different distribution of tone and tension in the numerous muscles of the body, are associated with different distributions of reflex irritability over the central nervous system Therefore one and the same stimulus may cause quite different reflex reactions according to the different attitudes of the animal at the moment the stimulus is applied

These short remarks may be sufficient to show to what extent the reflex behaviour of animals may be influenced by attitudinal reflexes The complexity becomes still greater if besides the bulbar centres with their relatively simple function higher centres come into play. This will be discussed in the next section

(*To be concluded*)

NEW GROWTHS IN THE THORAX

DIFFERENTIAL DIAGNOSIS FROM TUBERCULOSIS

By J M JOHNSTON M B Edin, D P H Lond,
PHYSICIAN SUPERINTENDENT TOR-NA-DEE SANATORIUM,
MURTLE ABERDEENSHIRE

THE six cases on which this paper is based have come under my own personal observation, and are used to illustrate the evidence which, in my opinion, should be taken into account in making a differential diagnosis between intrathoracic new growths and pulmonary tuberculosis

Clinical Histories

CASE 1 —A man aged 52, was admitted in October, 1922, with a diagnosis of "serious tubercular disease of the left lower lobe and a lesion at the right apex" His illness dated from October. 1921, when he had "influenza," followed by persistent cough In March, 1922, he had dry pleurisy at the left base, after which he began to lose weight rapidly, and had fever, with troublesome cough, pain in the left chest, and increasing weakness and dyspnœa. A physician who saw him diagnosed pulmonary tuberculosis, but considered tumour possible There were signs of slight infiltration at both apices without adventitious sounds, and evidence of fluid at the left base X rays showed fluid at the left base, and above the fluid a clear space bounded by a domed shadow The fluid was level and moved on inclining the patient, showing that there was air in the pleura, probably due to puncture of the lung by an exploring needle before admission Both apices were slightly infiltrated, and the heart was displaced to the right Some blood stained fluid was withdrawn and was sterile on culture, and no tubercle bacilli were found either in this or in the sputum. The fluid was aspirated, and the X rays then showed a dense shadow involving most of the lower lobe, which the radiologist and I regarded as highly suggestive of tumour The W R and the complement-fixation test for tuberculosis were negative There was a leucocytosis of 29,000, 86 per cent being polymorphs He had a few small hard glands above the right clavicle and one of these was dissected out and reported to be histologically tuberculous, but no T B were seen. He had vague digestive symptoms with slight epigastric tenderness Later he vomited some "coffee grounds," and with further rapid loss of weight a small tumour became palpable in the epigastrium This made a diagnosis of primary carcinoma of the stomach, with secondary deposit in the lung, practically certain and he was sent home. He died in February, 1923—i e, 18 months after the onset of his illness There was no post-mortem examination

CASE 2 —A female aged 42, two children, two miscarriages Admitted April, 1923, from another sanatorium, where the diagnosis was "tubercular cervical adenitis and tuberculosis *of the left* lung"

History —February, 1922, dry cough appeared, followed soon after by post-sternal pain and lassitude June, 1922, pulmonary tuberculosis was diagnosed, and she was sent to a sanatorium in September, 1922, and remained there till April, 1923 There was mild persistent fever all the time and cough and pain did not improve Once or twice the sputum was blood-flecked, but T B were never found, though the Pirquet reaction was positive Glands were noticed in the neck, and she was treated with tuberculin inunctions for six months Previous illnesses Aged 18, enlarged glands in neck for some months Aged 19, probable pleurisy at right base. Family history Mother died of fibroid phthisis, aged 73

Condition on Admission —Dyspnœa on mild exertion, fingers somewhat clubbed Complained of almost constant aching pain in the left chest, and there were mild fever and tachycardia There was a bunch of firm movable glands above the left clavicle, and a string of small glands along the posterior border of the sterno-mastoid, also enlarged glands in the left axilla The veins on the left side of the chest were prominent The left chest was flattened and expanded poorly, and vocal fremitus and resonance were decreased The percussion note was dull except in the axilla, the breath sounds were faint, and a few muffled rales were heard at the apex On the right side there was some intrascapular dullness on percussion and a few crepitations in the second interspace in front The heart was a little displaced to the right; there were no bruits By X rays the screen showed some displacement of the heart to the right, and the left diaphragm high and nearly immobile At the root of the right lung there was a small clearly outlined dark shadow, and on the left side a larger dark shadow with a clearly outlined natiform border—evidently enlarged glands This shadow was continuous with the mediastinal shadow and was non-pulsatile. The film showed the condition very well I obtained a print of a radiogram taken nine months previously and the change was very striking. The sputum was scanty, no T B found There was a leucocytosis of 20,000, of which 88 per cent were polymorphs The W R was negative but the complement-fixation test for tuberculosis was positive (possibly due to the tuberculin inunctions) A provisional diagnosis of Hodgkin's disease was made, and a gland was dissected out and reported by a pathologist as "typical lymphadenoma" She was obviously getting worse, and was sent home to have X ray treatment Temporary improvement resulted, but she died in September, 1924—i e, about two and a half years after the onset of symptoms

CASE 3 —A male aged 40, a medical man Admitted January, 1924, with a diagnosis of "acute pulmonary tuberculosis"

History —October, 1923, sudden pain over right lower ribs with fever and some cough. A doctor found doubtful friction at the right base. Two weeks off work and then felt as usual November, 1923, a second attack of fever with cough, and there were signs of a pleural effusion at the right base One c cm of blood-stained fluid was drawn off and was found to be sterile, though containing many polymorphs A blood count gave 30,000 leucocytes 70 per cent being polymorphs Fever persisted and dyspnœa and cough increased when he lay on his right side X ray examination "mediastinal mischief growing into the lung"; and as two T.B were seen in the sputum at the seventh examination, a diagnosis of pulmonary tuberculosis was made Previous illnesses · Pneumonia at 17, dysentery at 30, acute dyspepsia at 31, and at 34 severe indigestion for which he was invalided home from India as duodenal ulcer After a year's treatment he was practically well.

Condition on Admission —Poorly nourished, with pallor, cyanosis of the lips, and dyspnœa on slight exertion. He complained of constant aching pain in the right chest, and there was troublesome dry cough with glairy sputum. There were signs of some infiltration of the right upper lobe with a few crepitations and rhonchi behind At the right base were signs of a small fluid effusion. Nothing abnormal was made out in the left lung X ray examination showed moderate density at the right apex and a dense shadow above the diaphragm, suggestive of fluid, but also, above the level of the fluid, a dense non-pulsating shadow with an irregular but clear outline continuous with the mediastinal shadow On the left side the apex was not quite clear and the root shadows were somewhat pronounced. The heart was apparently sound. The radial pulses were equal There was a leucocytosis of 26,000, of which 80 per cent were polymorphs The sputum was examined repeatedly and eventually a few acid-fast bacilli were seen in a concentrated 24 hours specimen. Pneumococci were always numerous A specimen was sent to Dr J Cruickshank, who reported that "after concentration a few T B were seen," but he inoculated a guinea-pig with some of the sputum and reported later that "the guinea-pig remained quite well, and that the acid-fast bacilli found by concentration were probably not tubercle bacilli"

I explored the right base and got some turbid fluid which contained many cells of which 90 per cent were polymorphs No T.B were seen and no growth obtained on culture A guinea-pig inoculated with some of the fluid did not develop tuberculosis The W.R was negative, as also was the complement-fixation test for tuberculosis The patient improved at first, but six weeks after admission the sputum became constantly blood-stained and the cough ineffective A mouse injected with some of the sputum died of pneumococcal infection, and an autogenous vaccine was prepared but never given as the symptoms became urgent somewhat suddenly Dyspnœa increased greatly, and there were attacks of stridor with intense cyanosis and spasms of cough.

I asked Prof Ashley Mackintosh to see him and he agreed that malignant disease was the most likely diagnosis, though there was probable antecedent tuberculous infection. His symptoms were not relieved to any extent by oxygen, adrenalin or morphine, and he died in a few days No post-mortem examination was permitted

CASE 4 —Male, aged 32 Admitted August, 1924, with a diagnosis of "pulmonary tuberculosis of the right lower lobe"

History —Healthy man till December, 1923, when he had dry pleurisy at the right base with fever and hæmoptysis In bed one month and returned to work after another month May, 1924, another attack of dry pleurisy at right base with slight fever and hæmoptysis T B not found July 1924, had further hæmoptysis, lost weight, and dyspnœa became troublesome Saw a *consultant* who diagnosed pulmonary tuberculosis

Condition on Admission —Pale and ill-looking No special cyanosis, but he was dyspnœic on mild exertion and complained of constant aching pain of the right chest shoulder, reactions, all of them closely allied, yet each with its own immunity reactions The most prevalent meningococcus in this epidemic was of the second type

During the last three years 18 autopsies were performed In 15 the usual features of meningococcal meningitis were present Serous fluid and pus were found in considerable quantity beneath the meninges, and there was softening of the cerebral and cerebellar tissue In two cases the blood-vessels of the cerebral cortex and the vessels of the pia mater were markedly congested, the meninges were thickened and lustreless In one case the ventricles were greatly distended, and the brain tissue was much thinned and softened

Clinical History

Most of the cases admitted into the hospital were of the fulminating and ordinary types, and very few were of the chronic type. Scarcely any passed into the chronic stage after the adoption of serum treatment All the cases had the usual classical signs and symptoms of cerebro-spinal fever. The intensity of the different symptoms varied in most cases Some had marked retraction of the head Some had severe convulsions, and in others unconsciousness was a marked feature

Pneumonia was the most common complication The others were cystitis, bed-sores, and eye complications, such as corneal ulcers, perforation of the eyeball, panophthalmitis, squint, and temporary amblyopia Those due to serum treatment were swelling of joints, joint pains, and different rashes The following are the interesting cases illustrating some of the complications —

CASE 1 —(Perforation of cornea and squint) Patient, R M, aged 16, male, was admitted with usual symptoms of cerebro-spinal fever and swollen and painful wrist-joints Lumbar puncture was performed and serum injected Temperature came down to normal, but joints were swollen and painful Lumbar punctures were performed and serum injections were repeated on alternate days He developed corneal ulcer of the right eye, which later on perforated Afterwards he got a squint in the left eye, and the swelling of the joints subsided gradually Then he got a relapse with fever 105° F and shotty, papular eruptions on the face, hands, and trunk. After a few days the rash disappeared and the temperature came down to normal

CASE 2 —(Serum rash) Patient, V R, male, aged 15, was admitted with the usual symptoms of cerebro-spinal fever and marked retraction of head Lumbar puncture was performed and serum injected The patient was restless during the night, but on the next day the retraction was less and temperature was normal Further lumbar punctures were performed and serum injected on alternate days Then a punctate hæmorrhagic rash appeared on the face and extremities, and for a week he was a little delirious and complained of headache He began to improve after one lumbar puncture and serum injection, delirium lessened, headache subsided, temperature came down to normal, and finally he was completely cured

CASE 3 —(Joint pains) Patient, L A, female, aged 16, was admitted with the usual symptoms of cerebro-spinal fever and marked rigidity of neck and delirium Lumbar punctures were performed, and serum injections were given on alternate days She complained of severe headache and restlessness during all the days, and five days after the last injection she complained of pain all over the body and the right knee was swollen and painful, it gradually subsided, and she became quite well afterwards

CASE 4 —(Chronic type) Patient, D, male, aged 30, was seen with the usual symptoms of cerebro-spinal fever, unconsciousness, delirium, and pain in the chest Lumbar puncture was done, and serum was injected intrathecally Very turbid fluid came out under high pressure It showed many meningococci and polymorphonuclear leucocytes After five lumbar punctures and serum injections fever came down but fluid was still turbid The relatives did not allow more lumbar punctures as he was feeling better After one week he got fever and rigors, which the other consultants declared to be malaria, and he was put on antimalarial treatment, but the fever did not subside and Kernig's sign, retraction of head, stiffness of neck, and unconsciousness reappeared The serum treatment was started again, and after ten injections on alternate days the patient felt better, fever came down, incontinence of urine and fæces disappeared, and fluid was quite clear after five more injections, during this time he got thrombosis of the right femoral vein and bed-sores on both the hips, for which he was treated, the former were cured but the latter persisted He got better day by day, but could not walk or see with the right eye After 14 months he was able to walk on crutches, and five months later he was able to walk with a stick At present he is well, except for ankylosis of the right hip and loss of vision of the right eye. He had in all 19 lumbar punctures, and treatment lasted for 22 months

CASE 5 —(Afebrile type) Patient, K, female, aged 30, had intense occipital headache, retraction of head, and stiffness of neck and photophobia for three days Later she had dimness of vision There was no temperature Lumbar puncture was done Turbid fluid came out under high pressure, and showed many meningococci After three lumbar punctures and serum injections, headache and other symptoms cleared up There was no fever throughout the course of illness of 11 days

Resumé of Some of the Cases Treated Successfully with Serum

No	Initials	Age	Sex	Days of disease when serum was injected	Total amount of serum injected c c	Influence on temperature

Prognosis

It is extremely difficult to give prognosis in such a variable disease Sometimes apparently hopeless cases with coma recover (Case 4), while others, although looking better, prove fatal owing to sudden change in the inflammatory conditions of the meninges and brain, or to the subsequent development of hydrocephalus In this series all the fulminating cases died, and ordinary and chronic cases recovered with lumbar puncture and serum treatment from the beginning The mortality was heavy in infants and adults over 10 As a rule, mortality in this disease is very high, but general adoption of serotherapy, not only intrathecally but intramuscularly and intravenously, has reduced it a great deal At the municipal hospitals, out of 55 cases admitted and diagnosed as cerebro-spinal fever from clinical signs only from January to July 1921, 45 cases died showing a mortality of 82 per cent Later on, out of 96 cases in which lumbar puncture and serum treatment was regularly adopted, 52 died giving a mortality of 54 2 per cent

The mortality-rate is much lower in private cases which come under treatment early Out of 7 of these only 2 fulminant cases died showing a mortality of 28 5 per cent

Treatment

The treatment adopted was mainly specific—i e serum treatment, symptomatic treatment was resorted to whenever necessary. All the cases were treated by intrathecal injections of serum After the lumbar puncture 30 to 40 c.cm of the fluid was allowed to run out and an equal amount or little less serum injected by the gravity method This was done soon after the patients were admitted. and it was repeated daily or every other day. The serum used throughout was of polyvalent type prepared by the Lister Institute The best serum would have been that from the same strain of meningococcus which was the cause of the disease but owing to the great difficulties of obtaining such a serum polyvalent serum was used; although its potency is reduced to about a fourth it answered the purpose fairly well The use of the serum caused the turbid cerebro-spinal fluid to become clear, at the same time many patients were cured, the illness was cut short, and there were fewer sequelæ such as deafness, blindness, and paralysis In symptomatic treatment, the pain was relieved by local withdrawal of blood and counter irritation by leeches on the nape of the neck The temperature was lowered and the irritability lessened by applying cold to the head and spine (hydrotherapy) in the form of tepid baths To allay the spasms and tremors, bromides chloral and morphia were given internally Potassium iodide was given in later stages and helmitol was administered as an internal antiseptic especially directed towards the cerebro-spinal fluid

Conclusion.

I agree with Simon Flexner[4] "that the analysis of cases of epidemic meningitis which have been presented furnish convincing proof that the anti-meningococcus serum, when used by the subdural method of injection in suitable doses and at proper intervals, is capable of reducing the period of illness of preventing in large measure the chronic lesions and types of infection, of bringing about complete restoration of health in all but a very small number of the recovered; thus lessening the serious deforming and permanent consequences of meningitis and of greatly diminishing the fatalities due to the disease

BY AIR TO HOSPITAL.—The Real Daylight Balata Estates Limited, in British Guiana, has obtained from England a "Fairey" seaplane for the rapid conveyance of sick or injured employees from its station at Apoteri to Georgetown, 272 miles distant. The 'plane, which is especially adapted for tropical use, will carry one stretcher case and an attendant.

A CASE OF

INFECTION WITH BACILLUS DYSENTERIÆ (FLEXNER)

PRESENTING UNUSUAL SYMPTOMS

BY S F BREAKEY, M B, B CH. BELF,
RICHARD MURRAY HOSPITAL, BLACKHILL, CO. DURHAM.

With Bacteriological Notes by
F H A. CLAYTON M D, M.R C P EDIN

THERE is now sufficient evidence to show that in a certain proportion of cases the symptoms produced by the Flexner bacillus are entirely different from the classical symptoms of dysentery. Savage and Bruce White[1] have recently recorded a definite outbreak of food poisoning due to this organism and a somewhat similar series of cases with sudden onset was reported by Bainbridge and Dudfield[2] in 1911. although on this occasion food poisoning was considered improbable.

In the particular instance about to be described, although the initial history pointed to some acute alimentary trouble the divergence from the typical picture of dysentery was not so much in this direction as in the rapid development of an intense toxæmia producing a condition hardly if at all to be distinguished from the results of some gross cerebral lesion This finds an almost exact parallel in a case of Flexner infection reported by Marshall[3] in 1909

There was no opportunity of confirming the diagnosis of infection by examination of the blood or of the organs post mortem but the fact that the bacillus was readily isolated in considerable numbers from the fæces indicates the extreme probability that the illness was essentially the result of this infection and this opinion is likewise favoured by the absence of pathological evidence pointing to any other cause for the condition

As it is desirable that all anomalous cases should be put on record. the following brief account is given.

History of Case

As the progress of the illness from onset to death was extremely rapid (roughly 30 hours) the history is given in detail

The patient L M. was a female, aged 7, who had, with the exception of such childish ailments as measles and whooping-cough enjoyed excellent health and was described as a "bright child"

Throughout the day preceding the onset of her illness (Oct. 27th, 1925) she appeared to be thoroughly normal and at bedtime remarked to her father "I am full of 'vital.'" (vitality) She also slept well during the night Next morning the 28th, she performed the usual morning routine of breakfast and departure for school and the parents noticed nothing unusual At midday she was sent home from school, returning unwillingly, the reason given being that "she had been sick." She walked home and for the remainder of the day till 10 P.M. lay on a couch without complaint She was then given a seidlitz powder and walked upstairs, jumping over a couch en route, undressed herself, and went to bed. Throughout the night, however, she was very restless and "rambled and talked in her sleep" She got up unaided "twenty or thirty times" to go to stool but passed very little although no blood or slime was noticed and she had no vomiting Next morning, the 29th, as she seemed "excited and strange in her manner," the doctor was summoned and saw her at 9 30 A.M. when he advised her removal to hospital, where she was admitted at 12 15 P.M. with a suggestion from him that the case might possibly be an acute abdomen.

On admission she was semi-delirious and complained of headache Knee-jerks exaggerated, pupils dilated, and there was photophobia Temperature, 102 6° F; pulse, 140 Decubitus Left lateral with flexion of thighs and legs. Examination of heart and lungs revealed no abnormality and no rigidity, tenderness, or distension could be found in the abdomen.

By 2 P.M. complete unconsciousness supervened and a small quantity of bile-stained fluid was vomited. Convergent squint of left eye was noted, but there was no retraction of head and Kernig's sign was indefinite At 2 30 P.M. a soft ribbon stool of yellowish-green colour, homogeneous, non-offensive, and free from visible blood or mucus was passed This was the only stool observed in hospital and resembled a magnified worm cast At 3 P M retraction of head, twitchings, and spasticity of the limbs, and a markedly positive Kernig were present Lumbar puncture was now performed and yielded a clear fluid not under tension. A rectal swab was also taken

---

[1] Special Report No 92 of the Medical Research Council

[2] Journal of Hygiene 1911 xi, 356

[3] Journal of the R.A.M C., 1909, xii., 556

From this time the patient passed into an ever-deepening coma, head retraction became extreme, and the pulse uncountable Death supervened at 5 30 P M and a nasal swab was taken immediately afterwards These three specimens were despatched to the College of Medicine Laboratory at Newcastle-on-Tyne by the evening post

Post-mortem Examination

Permission was at first granted for a partial post-mortem only (chest and abdomen) and this was performed at 10 o'clock The abdominal contents appeared quite normal The intestines showed nowhere to the naked eye signs of congestion or injection and the appendix was freely movable and appeared healthy. A slight quantity of clear fluid was present As the symptoms in hospital had been mainly cerebral and there was little to indicate an intestinal infection, no segment was removed The heart and lungs were normal Next morning at 11 o'clock further permission was obtained to examine the brain. This, on surface and section, showed no signs of inflammation, no congestion of vessels, except slightly in the basilar region round the pons, and no pus, turbid fluid, or tubercles

In the absence of a bacteriological report, and in view of the post-mortem findings, the tentative diagnosis of encephalitis lethargica (fulminating) was made for the purpose of certification

Bacteriological Notes by DR CLAYTON

The three specimens were received from the Richard Murray Hospital, Blackhill, on the morning of Oct 30th, 1925

The first was a nasal swab, from which no growth except *Staphylococcus albus* was obtained

The second specimen was cerebro-spinal fluid This was an absolutely clear fluid showing no trace of coagulum An absolute count with a Fuchs-Rosenthal chamber showed a few red but no white cells in 64 squares, and films of centrifuged fluid confirmed this, showing only an occasional lymphocyte with a few obviously contaminating organisms

Chemical tests, carried out by my colleague, Mr H R Whitehead, gave the following results Total chlorides, 0 728 per cent , total proteins, 0 02 per cent , globulin test, negative The fluid was consequently reported as to all intents and purposes normal

The third specimen received was a rectal swab which was covered with what was apparently normal fæcal material without any sign of blood or mucus and which was still moist, despite the fact that it had been collected on the previous afternoon at 3 o'clock From this MacConkey plates were sown and next day numerous clear colonies were visible Six were picked off and sown in media containing lactose, glucose, and mannite As all six organisms produced acid in the latter two and left lactose unchanged, an agar slope sown at the same time was emulsified in saline and tested against the Oxford polyvalent Flexner and typhoid sera The former agglutinated to 1 in 125 after four hours; the latter showed no trace

Unfortunately, it was impossible to acquaint Dr Breakey with these results in time to give him any guidance, as the patient was dead and the post mortem had been performed almost before the specimens had been received at the laboratory

As the isolation of a dysentery bacillus was decidedly unexpected and a chance observation, and the time occupied in the transmission of the specimen somewhat prolonged, special care was taken to confirm its identity and the results are given in some detail

The complete reactions of the organisms when tested for three weeks proved to be those of *B dysenteriæ* (Flexner) In all subsequent agglutinations the Dreyer technique was adopted and 24-hour peptone cultures were used The results were read with the assistance of the Oxford dark-ground apparatus and were repeated With the 24-hour peptone cultures all six strains agglutinated to 1 in 250 with the Oxford polyvalent serum Tested against the five Oxford strains of Flexner Z showed no trace of agglutination X and Y agglutinated to about 1 in 50, Y to 1 in 250, and W to 1 in 600 Finally an antiserum was prepared and when tested against the organism itself this agglutinated to 1 in 10,000 With the Oxford strains it agglutinated W to the same extent, Y to 1 in 2500 and the others only slightly.

Commentary

This case appears to fall into line with the limited number in which an infection with the Flexner bacillus has given rise to symptoms which are very different from the classical picture of dysentery Together with Marshall's case it demonstrates the fact that such an infection, like so many other conditions in children, may on rare occasions simulate gross cerebral lesions. An accurate diagnosis was practically impossible until the bacillus had been isolated for, after admission to hospital, the cerebral condition entirely dominated the clinical picture It is interesting to find that so delicate an organism should have survived in such large numbers the somewhat prolonged journey

No other occupants of the house partaking of the same food were affected It was thought that some relative might possibly have been a dysentery carrier, and inquiries made by one of us (S F B) pointed to an uncle of the child as a potential source She was constantly playing in his house and it was found that he had served about three years in Mesopotamia, and although he himself had only suffered from sand fly fever, had been in close contact for some months with a dysentery case His stools, however, proved negative on two occasions

OBSTRUCTION OF THE ŒSOPHAGUS

CAUSED BY A PERSISTENT DUCTUS ARTERIOSUS

BY A J JEX-BLAKE, M D OXF, F R C P LOND

With a Note on the Condition by

SIR ARTHUR KEITH,

CONSERVATOR OF MUSEUM, ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE case set out here, although only that of a lurcher pup which had great difficulty in swallowing, is worthy of record for several reasons The nature of the œsophageal obstruction was most puzzling and obscure, but a post-mortem examination has revealed the fact that this pup was slowly starved of food and of oxygen by the natural contraction of the ductus arteriosus, and that, if the condition had been diagnosed, relief could have been given by a simple surgical operation The late Mr C B Lockwood presented to the Museum of the Royal College of Surgeons the thoracic parts of an individual who presented the same anomalies of the aorta and ductus arteriosus as occurred in the case of the puppy recorded here, but in Mr Lockwood's case there was no difficulty in either breathing or swallowing, because the cord of the ductus arteriosus had undergone a sufficient elongation to allow food and air to pass

A search of medical literature has not yielded a single case in which the œsophagus was constricted by a ductus arteriosus As will be seen from the illustration, the œsophagus and trachea passed through an arterial ring or noose, formed by the arch of the aorta to the right, and the pulmonary artery and ductus arteriosus to the left After birth, as we now know the ductus arteriosus in this pup became empty, its lumen became obliterated, forming a cord which steadily shortened and thus drew the arterial noose tight upon œsophagus and trachea. A brief description of the specimen will be given by Sir Arthur Keith here I propose to set out the remarkable clinical history of this case

Clinical History

In the course of breeding lurchers near Nairobi, Kenya Colony, the following condition was met with in a puppy A litter of ten was born in September 1924, the dam being an imported pedigree English greyhound bitch by a French lurcher from an English greyhound the sire a crossbred pointer dog Seven of the ten puppies were kept all appearing to be normal in every way After the third week it was noticed that one of them named Hubert was often sick in the middle of suckling After the fourth week the dam's milk was supplemented with feeds of bread-and-milk two or three times a day, and Hubert was seen to be almost always sick in the middle of these meals, immediately lapping up the vomit He seemed to have pain in the abdomen before vomiting, and sometimes scratched at his neck with his front paws just before he did so None of the other six puppies was ever seen to be sick The dam went dry after the sixth week, by which time the litter was being fed on milk, rusks, sweet potato and meat given thrice daily In spite of the frequent vomiting Hubert did pretty well for the first six weeks, as is shown by the following table of the puppies' weights in ounces —

At birth	Age in weeks—	1	2	3	4	5	6	7	8	10	17
oz 15	Hubert	27	43	56	78	104	114	113	150	222	560
15½	Average of six other puppies	31	59	68	83	111	143	168	203	250	496*

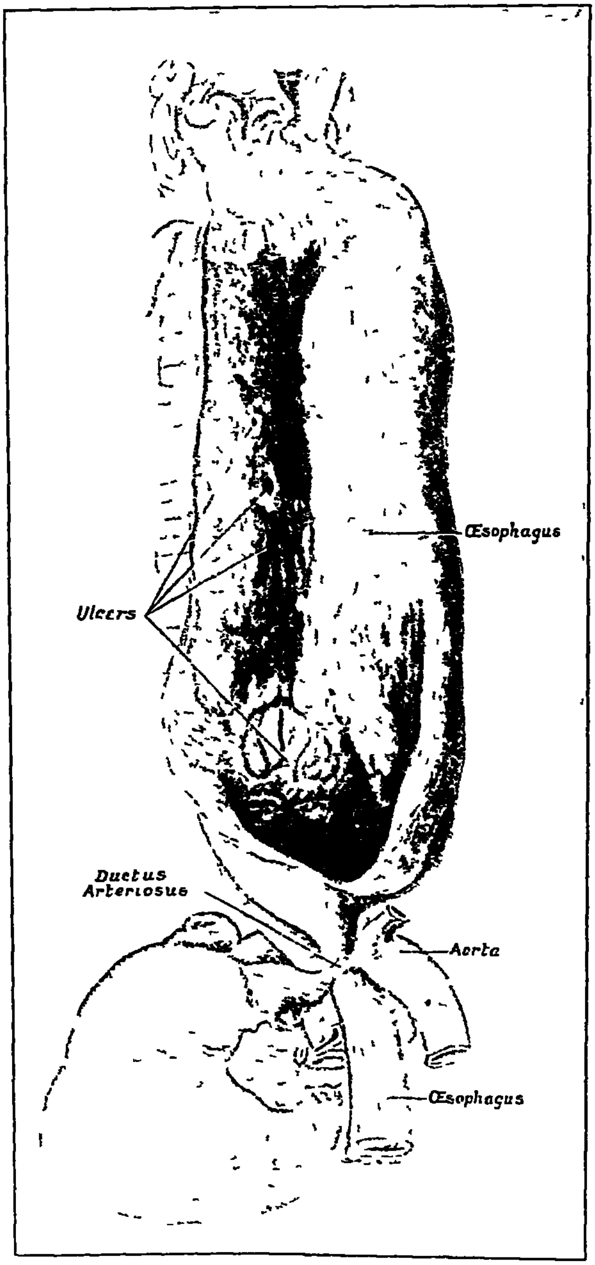
* Weight of one puppy only

It will be seen that during the seventh week Hubert lost an ounce in weight, while the other six gained on an average 25 oz each. At this time he was usually vomiting two or three times in the course of each meal, snuffling much through the nose, and making rattling noises in his throat which ceased when he had been sick. There was no cough and no discharge from the nose With the idea that he might have worms (flat or round, common in Kenya puppies) he was dosed twice with Sewell's santonin mixture, but without either improvement or the evacuation of any worms

Up to this time no diagnosis of the cause of the vomiting had been made When he was seven weeks' old it was noticed one day after a meal that Hubert had developed a soft, symmetrical, bulging and fluctuating tumour in the lower part of his neck, behind the wind-pipe and going down below the sternum This tumour disappeared when, after much palpation of the neck, he was sick and brought up about 2 oz of unaltered bread-and-milk taken two hours previously and only faintly acid to litmus paper It was then apparent that there was some obstruction about the lower part of the food-pipe, and it was thought that this was probably due to spasm at the cardiac end of the œsophagus rather than to the pressure of some new growth He was accordingly put on to a special fluid diet of milk, raw eggs, sugar and small pieces of butter, beaten up together and given four or five times a day, together with five or six drops of tincture of opium in each feed to relieve the supposed spasm. During the next (the eighth) week Hubert put on 37 oz in weight, the other six puppies averaging an increase of 35 oz, showing that the new diet was a success, there was very little vomiting How far the tincture of opium contributed to this success seemed doubtful, as it appeared to have no general effect on the puppy whatever, and after nine or ten days it was discontinued At this time, and subsequently, Hubert was running about the kennel and large enclosed yard with the other puppies, and it was not always possible to prevent him from getting hold of scraps of their solid food and bones from time to time, these he used to bring up again, but his own feeds he mostly kept down He also used to get solid food occasionally from his dam, who would jump into the puppy enclosure at odd times soon after her own meals and vomit up without effort a quantity of her dinner, this was always ravenously devoured by the puppies at once, although they might have been unable to finish their own dinners a few minutes previously Twice Hubert was seen to bring up gobbets of meat and sweet potato got hold of in this way soon after he had had his own fluid dinner on each occasion his own dinner failed to reappear showing that it had got safely through the œsophageal constriction into the stomach

At the end of the ninth week he was given some meals of boiled maize meal porridge and milk, which were gulped down hastily and tended to fill up his œsophagus it was found that if he was then held up in an upright position, and his neck was gently stroked, the œsophagus would slowly and jerkily empty itself into the stomach with a mixture of gurgles and clicks Hubert meanwhile making swallowing movements with his pharynx No œsophageal peristaltic movements could ever be detected in his neck

Much time and trouble were devoted to his feeding and during the tenth week he put on 46 oz five others of the puppies increasing by 25 oz each on the average At this time and for the rest of his life Hubert was a particularly lively and well liking puppy full of character, always hungry, and, like other puppies constantly picking up and swallowing scraps of all sorts, bones, small stones, lumps of earth, grains of maize, leaves, grass, cow-dung, pellets of goats'-dung (always particularly attractive, it seems), and so forth, when running about the farm and garden and when out walking These solids, of course, blocked and distended his œsophagus, and the distended œsophagus would press on his trachea and deform it against the back of his episternal notch with the result that his breathing became very wheezy and noisy and his activity diminished He would then stand still with his fore legs splayed out his head forward and his mouth a little open wheezing, sometimes in the course of a walk when he was in this state, one could lead him to fill up full on cow- or horse-dung, the only available pabulum, and then holding him upside



Drawing (7 12 natural size) of the œsophagus trachea and heart of a lurcher killed when 17 weeks old The œsophagus and trachea are seen to pass between the ductus arteriosus exposed on the left and the arch of the aorta which passes to the right of these two structures The ductus constricts the œsophagus which is greatly dilated and hypertrophied above the side of constriction The trachea is also caught within this vascular ring and its lumen is reduced to half the normal diameter The dilated part could hold 23 oz in life down, get him to vomit the lot, this being successfully accomplished he would recover his breath and his activity at once.

After the twelfth week Hubert had three meals a day, and a routine developed in their administration His neck was first examined for signs of distension of the œsophagus, and if this seemed absent he was given his fluid meal If this did not go down, but began to bulge out his œsophagus, or if he started with a distended œsophagus, he was held up in an upright position for a time in the hope that its contents would work through into the stomach If they did not do so and the œsophagus remained distended, he was encouraged to gorge himself on maize-meal-and-water porridge (a cheap food) until the œsophagus was distended right up to the lower jaw, until, in fact, he was full up to the neck. He was then held upside down over an empty pie-dish and gently shaken up and down until he was sick, the vomiting almost always took place without effort and in a single rush, and last of all would come out some solid substance picked up in the farm or garden that had lodged at the bottom of the gullet and prevented the passage of the liquid food into the stomach He seemed unwilling to part with the contents of his œsophagus, and could not be made to vomit at all unless the œsophagus was pretty full, once it was emptied in the way described above he would take his fluid meal of milk, eggs, sugar and butter, or his thin porridge of maize-meal and milk, with great appetite and success

During the last three weeks of his life Hubert's œsophagus had to be cleared out before meals in this way with increasing frequency, it held about 11 oz when he was 12 weeks old, and about 23 oz at 17 weeks Latterly it was found that he did not always clear his œsophagus when made to vomit, and that it might be necessary to make him sick two or even three times before liquid food could get on into the stomach, so that it took half or three-quarters of an hour to feed him At 17 weeks he weighed 35 lb, and it became rather an effort to hold him upside down for as long as might be necessary to induce vomiting, and sometimes the liquid food seemed to cause pain as it went down, giving rise to the suspicion of some ulceration at the lower end of the œsophagus, though no blood was ever seen in the vomit It was felt that his condition was incurable, and so, with great regrets, he was killed by chloroform when 123 days old At the same time another puppy of the same litter, named Hannah, weighing 32 lb, and suffering from a recent slowly progressing paresis of the hind legs for which no cause was found—it may have been traumatic in origin—was chloroformed, and dissected for purposes of comparison

Description of Specimen by Sir Arthur Keith

The chief structural abnormalities are shown in the illustration The arch of the aorta has persisted on the left side—as in birds—instead of on the right, the branches of the arch coming off in the following order right carotid, left carotid, right subclavian, left subclavian, just as in Mr Lockwood's specimen (No 566 1, R C S Museum) The ductus arteriosus passes across the left side of the œsophagus from pulmonary artery to the arch of the aorta, at the origin of the left subclavian, forming a cord 20 mm long and 5 mm in thickness The œsophagus, where constricted by the ductus, has a diameter of 10 mm, its lumen being only 3 5 mm in diameter Above the constriction the œsophagus has a circumference of 150 mm, whereas in the normal dog this measurement is only 60 mm The muscle coats of the retrotracheal part of the œsophagus of the normal dog had a thickness 0 02 mm, whereas in the dilated œsophagus the thickness is 0 05 mm Thus, as a result of constriction, the muscular coats in the retrotracheal segment of the œsophagus of the ailing pup had undergone a hypertrophy of about six times the normal amount The mucous coat had also undergone a general thickening, expansion, and hypertrophy, and had become infected and ulcerated at many points The dilatation of the œsophagus pressed upon the trachea, particularly the part above the arch of the aorta, so that this part, and particularly the segment which is engaged within the arterial ring or noose, was only 12 mm in diameter, whereas in the normal dog of the same age it was 18 mm in diameter

The case is very remarkable in many ways, for it is not often we find Nature killing her progeny by her own devices Normally the arch of the aorta and ductus arteriosus lie on the same side of trachea and œsophagus, but in this case they formed a ring round them It was not until the pup was three weeks of age that symptoms of œsophageal obstruction were observed, obliteration and shortening of the ductus arteriosus proceeded apace in the second week, and by the third the ductus began to constrict the œsophagus Much has been written as to the clinical manifestations of a persistent ductus arteriosus, but this appears to be the first case in which it was found to have caused death by constricting the food and air passages The dissection represented in the figure was made from Dr Jex-Blake's specimen, and is preserved in the teratological section of the R C S Museum, its number being 566 15

Clinical and Laboratory Notes.

EXCESSIVE INSULIN DOSAGE IN DIABETIC GANGRENE

By Howard F Root, M D,
NEW ENGLAND DEACONESS HOSPITAL BOSTON, MASS, U S A

In The Lancet of May 23rd, 1925, Dr Carrasco de Formiguera has criticised the use of doses of insulin in cases of diabetes with infection, which failed to make the patient sugar-free and to maintain a normal blood-sugar content That the use of large doses of insulin in such cases may be not only expensive and needless, but actually dangerous, should be remembered by physicians, and for this reason I wish to record the following case, seen in consultation at some distance from Boston, on Dec 27th, 1925

Housewife, aged 51 years Diabetes was discovered in 1914, and she had been treated by various physicians during the intervening period without satisfactory coöperation on her part Four weeks previously, because of a black, painful toe on the right foot, she entered a hospital where the treatment of diabetes is an exception Her temperature was 101 6° F, and the urine contained 2 7 per cent of sugar The toe was amputated on Dec 5th, but the fever continued The wound did not heal, and three weeks later the leg was amputated below the knee Fever still persisted The stump became discoloured and gangrenous, and the patient became weaker Although the urine had been sugar-free constantly after the third day in the hospital, the dose of insulin was steadily increased in the attempt to get a normal morning blood-sugar The following table, kindly placed at my disposal, gives the analyses up to and including the date upon which I was first consulted

Fatal Hypoglycæmia with Sepsis and Uræmia

Date 1925		Urine sugar per cent	Blood sugar per cent fasting	Temperature Degrees F	Insulin daily Units
Nov	30th	2 0	0 40	101 6	—
Dec	4th	0	0 14	101 2	60
	5th	0	0 20	100 0	60

* Non protein nitrogen of the blood 86·0 mg per 100 c cm.
† Non protein nitrogen of the blood 185·0 mg per 100 c cm

Examination revealed an apparently dying woman, eyes rolling, stomach contents drooling from the mouth, almost pulseless, unresponsive, but with moist skin Hypoglycæmia was diagnosed A blood specimen was drawn immediately for chemical analysis, and with the same syringe and needle 10 g glucose in 50 per cent solution were given intravenously She responded promptly and within a few minutes answered questions rationally Within an hour she again relapsed, and a second intravenous injection of glucose gave immediate improvement Later, I understand, a third relapse followed, and she died before glucose could be given.

The blood-sugar percentage at 5 30 P M immediately before the first injection of glucose proved to be 0 015

Fortunately, although the immediate cause of death was clearly hypoglycæmia due to an overdose of insulin, one can honestly state that the prognosis was already hopeless owing to the sepsis and uræmia On one day in September, 1925, in the wards of the New England Deaconess Hospital, 15 diabetic patients were under treatment for gangrene or infections of the feet Six required no insulin, and the average dose of insulin for the other was but 16 units a day It is rare that a diabetic patient, except in coma, requires 50 units of insulin a day for more than a few days An abnormally high blood-sugar before breakfast does not justify large doses of insulin throughout the day unless the urine continues to contain sugar, or the blood-sugar percentage is at all times above normal When large doses of insulin are being given, the blood-sugar should be determined not only fasting, but also in the late forenoon or mid-afternoon as well until one is familiar with the case [1] A safe and simple rule for the use of insulin in the presence of infection when examinations of the blood cannot be made is to test the urine before each meal and at 10 P M, and give insulin at these times only if sugar is present If the urine is sugar-free and hyperglycæmia is later proved present, a moderate increase in insulin may be used

A CASE OF PNEUMOCOCCAL MENINGITIS

ORIGINATING FROM AN OCCULT SINUSITIS

By ISABEL FALCONER KING, M B EDIN,
D P M LOND,
SENIOR ASSISTANT PHYSICIAN, RUBERY HILL MENTAL HOSPITAL, BIRMINGHAM

IN this case the course of the disease was extremely rapid the origin of the infection from the sinusitis was very definite, and the existence of the sinusitis unsuspected

E H, a woman aged 36, a case of dementia paranoides, who was apparently in good health save for some shortening of cardiac diastole, during the first week of January, 1926, was noticed to be slightly irritable in temper—a most unusual state for her as she was of cheerful habit and tended to be exalted—but made no complaint of illness

Jan 7th Early in the morning she vomited and complained of headache Temperature, 97 4° F, pulse, 80, respiration 20 She was kept in bed At 6 P M., T 103°, P, 96, R, 24 No localising signs were found on examination

8th 10 A M T, 101 4°, P, 96, R, 24 She was restless, confused, and resistive, but did not yet present any localising signs At 6 P M. T 100 2° F, P, 106; R, 24 Kernig's sign positive on both sides and head retraction present She was much confused and very resistive, lumbar puncture being impossible

9th 1 50 A M. She had a convulsion of an apoplectic character After this she was comatose, the respiration being stertorous and tending to Cheyne-Stokes in type The pulse was full and bounding There was paralysis of the left face and right arm and leg The plantar reflex was extensor on the right There was skew deviation of the eyes The pupils were contracted, equal, regular, and non reactive 10 A M. T, 102° P, 98 R, 36 6 P M T, 101 8°, P, 12- R, 38 During this time she became rapidly worse The plantar response became extensor on both sides

The coma deepened, and she died on Jan 10th at 12 30 P M T, 108 2°, P, 98, R, 41

Autopsy—The body is well nourished and shows the usual post-mortem rigidity and lividity There are no bed-sores nor external signs of injury of recent origin The skull cap is normal The brain surface is the seat of a diffuse generalised leptomeningitis, the sulci being filled with greenish pus The tip of the right frontal lobe is adherent to the frontal plate of the ethmoid and to the cribriform plate The basal subarachnoid spaces are full of greenish pus The substance of the brain shows no macroscopic lesion. The right frontal, right ethmoidal, and the sphenoidal sinuses contain pus, most marked in the last named The cerebral vessels are healthy except in so far as they are surrounded by pus leading along the various sulci. The myocardium is somewhat fatty The endocardium is healthy except for some roughening of the tricuspid cusps Aorta and coronaries normal Lungs show no definite pathological change beyond some œdema of both bases Nothing noteworthy in abdominal viscera.

Bacteriological Report—Swabs from brain, frontal ethmoidal, and sphenoidal sinuses, direct smears all showed a Gram-positive capsulated diplococcus which was overgrown by contaminating organisms on cultivation.

The fact that there were no signs or symptoms to suggest a sinusitis during life is interesting

I am indebted to Dr T C Graves, medical superintendent of the Rubery Hill and Hollymoor Mental Hospitals, for permission to publish this case

SCARLET FEVER ANTITOXIN

IN A CASE OF ENDOCARDITIS AND MYOCARDITIS

By E S TOOGOOD, M A OXF, M R C S ENG,
CORONER FOR EAST CORNWALL.

THE following case of a severe infection of the heart, in which treatment with scarlet fever antitoxin was used, and was followed by complete recovery, appears to be worth recording

The patient, a girl of 11, had contracted diphtheria at school and was discharged from the sanatorium some two months previously after negative throat cultivations had been secured When I first saw her she was suffering from an acute tonsillitis which responded to treatment on the usual lines Three weeks later I was called in again as she had developed another sore-throat and had a temperature of 102° F The temperature was maintained for several days at this level with slight morning remissions the pulse-rate was persistently raised, being 132 to 144, the heart was dilated, and a double bruit was audible at the apex The tonsils quickly cleared up under treatment, but the cardiac signs remained unaltered and a tentative diagnosis of carditis, involving both the endocardium and the myocardium, was made This was confirmed by Dr A B Soltau, of Plymouth, who suggested the trial of scarlet fever antitoxin, as the condition was so strongly suggestive of a streptococcal infection originating in the throat

Three doses of the serum were given, each of 10 c cm, at intervals of four and nine days Careful desensitisation was carried out before the first dose was given, having in mind the fact that the child had quite recently had anti-diphtheritic serum, and no anaphylactic symptoms ensued Shortly before the second dose of serum typical petechial spots appeared but these quickly faded after the second dose Immediately after the second dose the temperature began gradually to subside reaching the normal in a few days and only rising again to 99° for one day after the third dose The pulse-rate took longer to fall to normal and did not reach 80 for seven weeks The cardiac bruits disappeared entirely, and the child, when seen quite recently, was in her usual normal health, with no discoverable cardiac lesion

Considering the severity of the infection, and the grave prognosis which was given, the prompt response to the use of the serum (Parke, Davis and Co preparation was used) was striking. and it suggests that this method of treatment may be of great value in dealing with these very grave conditions

DONATIONS AND BEQUESTS—Miss Mary Dorsett Foster, of Bloxwich, Staffs, left £735 to the Royal Orphanage, Wolverhampton, and £100 each to the Walsall General Hospital, and the Walsall Victoria Nursing Institution —Mr John Henry James Hornsby, of Cuckfield Park, Sussex, after several personal bequests left all his other property, which amounts to about £60 000, "for such charitable purposes and objects as I shall hereafter by codicil direct and in default of and subject to any such directions as my trustees in their uncontrolled discretion shall decide" No such codicil is filed with the will —Mr Robert Dixon Steele, of Prenton, Cheshire retired chemical manufacturer, left over £7000 to charities, including £1000 each to the Liverpool Royal Infirmary, the David Lewis Northern Hospital, the Liverpool Royal Southern Hospital and the Liverpool Stanley Hospital, £500 each to the Liverpool Maternity Hospital, the Hospital for Women, Shaw-street, the Children's Convalescent Home, West Kirby, and the Royal Liverpool Seamen's Orphanage

BRITISH MEDICAL ASSOCIATION

ANNUAL MEETING AT NOTTINGHAM

(Continued from p 500)

SECTION OF LARYNGOLOGY AND OTOLOGY

Wednesday, July 21st.

Dr. **Brown Kelly** (Glasgow) presided over this Section. The first morning was devoted to a discussion on the treatment of

Malignant Disease of the Upper Air and Food Passages

Mr F J **Steward** (London) read the opening paper, in which he dealt with the principles of surgical treatment. He discussed the subject under four headings (1) Selection of Cases, (2) Preparation, (3) Operation, (4) After-treatment. In selecting patients for operation it was convenient to divide them into three groups—favourable, doubtful, and hopeless. Doubtful cases made up about 50 per cent of the total number seen, 40 per cent. being practically hopeless when brought up, and less than 10 per cent being really favourable cases. As to preparation, while recognising the extreme importance of oral sepsis, he was inclined to favour methods less drastic than those considered imperative by some operators in recent years; he recommended painting infected tonsils with 1 in 500 chinosol in glycerine. In connexion with the operation, he advocated the use of the intratracheal insufflation of ether; he reviewed the methods of approach in various regions, emphasising the importance of repairing the wound as a definite third stage of the operation. As to after-treatment, he recommended feeding by passing a soft rubber catheter obliquely through the wound in the neck into the pharynx. The pharyngeal wall and skin should be fixed tightly round the catheter so that it does not slip out and there is no leakage.

X Rays.

Dr **Robert Knox** (London) gave an account of the treatment by means of X rays in these regions where the small area containing a large number of structures makes it difficult to restrict the beam of rays accurately to the parts under treatment. It was essential, further, that the skin and subjacent tissues should not be damaged, and the limited depth of tissue available presented another difficulty. At the present time higher voltages enabled a greater intensity to be applied at a given depth, whilst working at a greater tube distance. Filters on the skin of 2 to 10 cm of wax aided the operator in giving a strong dose at a depth with no risk of damage to the skin. The exact technique applied on these principles was described by Dr Knox, and also the method of estimating the appropriate dose, which was usually given in fractions at short intervals. The results, he said, had now greatly improved. He recommended pre-operative treatment in cases complicated by widespread glandular involvement. In inoperable cases X rays were used with no hope of cure but to alleviate the symptoms, with a certain measure of success. The outstanding feature in the improved technique had been the recognition that it was neither necessary nor advisable to adopt the lethal dose of Seitz and Wintz as the unit of effective dosage, but to take this as a unit of measurement of the total dose, which would be spread over days, weeks or months, according to the urgency of the case.

Radium

Sir **William Milligan** (Manchester) discussed treatment by means of radium, and foreshadowed the time when, with improved technique and a more accurate knowledge of dosage and duration of exposure, radium would be used in operable as well as inoperable cases. For the present his remarks were confined to the vast and distressing array of inoperable cases. There were two schools (1) those who believe in large doses and short exposures, and (2) those who believe in small doses and long exposures, to which latter Sir William Milligan himself belonged, the exposures being continued up to 10, 14 or even 21 days. The conclusions which he had reached were as follows (1) that in the present state of our knowledge surgical removal of a malignant growth should be undertaken if a practical proposition, (2) that the lymphatic nodes into which the lymph stream from the growth drains should be removed by dissection or by block dissection, (3) that the lymphatic vessels between the growth and the infected nodes should be irradiated either from within or by external irradiation, preferably by the former method, (4) that the growth to be irradiated should, wherever possible, be exposed so as to admit of its being handled. (5) that the introduction into the growth of a large number of seeds containing small doses of emanation to be retained in situ gives even better results than the implantation of screened tubes; (6) that the introduction of the seeds should follow a definite mathematical plan, (7) that as the periphery of the growth is reached the emanation dose may be reduced; (8) that ligation of the main artery to the growth should invariably be carried out.

Surgical Diathermy

Dr W S **Syme** (Glasgow) said that the value of surgical diathermy in the treatment of malignant disease of the mouth and throat decreased as the site of the disease descended from the alveolus to the œsophagus. The most suitable cases were those confined to the mouth, including the tongue, jaws, palate, fauces and floor of mouth. Dental sepsis must be treated as for an ordinary operation. As diathermy would not seal larger vessels, one or both lingual arteries or one or both external carotids might have to be ligatured. A preliminary tracheotomy might be advisable. Affected glands should be removed before or after the main operation. In some cases glands which appeared to be inoperable become operable after the removal of the primary growth and the sepsis attendant on it. In dealing with the growth itself the aim should be complete removal, first coagulating the tissue all round the tumour and then removing it, or its destruction in situ. The former was the better method. In inoperable cases, however advanced, much relief followed surgical diathermy. While diathermy caused remarkably little immediate shock, delayed shock could not be excluded, and experience taught that care must be exercised in regard to the duration of exposure to the diathermy current at one time. Dr Syme gave statistics of 122 cases treated by this method during the four years 1922–25. Of these 30 were alive on May 31st, 1926, varying from over six months to over four years after operation, 13 having survived for more than three years without recurrence. He claimed that in the treatment of malignant disease of the mouth the method of removal by diathermy was preferable to any other.

In the discussion which followed these four papers a large number of visitors took part, including Dr **William Hill** (London), who gave a demonstration of the technique of applying radium in the treatment of œsophageal cancer and Prof H **Neumann** (Vienna) who spoke of the use of intravenous injections of sugar as an auxiliary to X ray treatment.

In the afternoon Mr A R **Tweedie** and Mr **Bell Tawse** showed laryngological cases, including many which had been successfully treated by operation for malignant disease. These patients, amongst whom was a man with an unusually large pharyngeal pouch, formed the basis of a discussion.

Thursday, July 22nd

The second morning was spent in a discussion on the

After-treatment and Results of Mastoid Operations,

Mr **Norman Patterson** (London) presiding. The opening papers by Mr G J **Jenkins** (London) and Mr J S **Fraser** (Edinburgh) dealt respectively with the operations for acute disease and with the radical mastoid operation.

Operation in Acute Disease.

Mr. Jenkins insisted upon the importance of adequate drainage, and pointed out that primary suture with or without the use of antiseptics sometimes fails, and that such a failure might prove to be a matter of grave concern. Primary suture was preferable to secondary, and was unsafe when extensive irregular cavities prevented the soft parts from being brought into intimate contact with the deep bony parts. If this method was attempted it should be only in cases where the soft tissues fell in contact with the bone. There were two other considerations, the general condition of the patient and the character of the pus. If the pus was thin and watery, indicating inadequate local resistance, primary suture was contra-indicated. Primary suture sometimes failed even in selected cases, and even when it was successful the result was not always satisfactory. Mr. Jenkins advocated treatment by maintenance of an open wound, and he failed to see any advantage in favour of meatal drainage over drainage from the lower part of the mastoid wound. The advocates of meatal drainage appeared to be biased by the pleasant appearance of a healed postaural incision. Mr. Jenkins gave a detailed account of his technique in the management of the postaural wound, and warmly supported secondary suture which rarely failed if carefully done and gave the best cosmetic result of any of the methods of treatment.

The Radical Mastoid Operation.

Mr. Fraser, dealing with the radical and modified radical operations, did not favour Barany's suggestion of omitting the meatal plastic and leaving the postaural wound open. He recommended making a large meatus by means of Korner's plastic operation. He confirmed the claim of H. J. Marriage that if skin grafts are used the operation cavity heals more quickly, the outline of the inner wall is preserved in almost all cases, that the duration of the treatment is reduced, that a dry cavity results in a larger percentage of cases than with other methods, and that the resulting hearing power is better. If a graft is not applied, he held, the after-treatment is more troublesome on account of the formation of excessive granulations, which grow up from the facial spur and downwards from the cut edge of the attic and aditus. Thus a membrane tends to form about the level of the isthmus, shutting off the deeper part of the cavity. In any case it is necessary to clean out wax and epithelial accumulations at regular intervals. Mr. Fraser gave a valuable statistical record of the after results of 628 radical operations. After grafting a satisfactory result was obtained in 83 per cent., and the hearing improved in 61 per cent. Without using skin grafts a satisfactory result was obtained in 52 per cent., and the hearing improved in 44 per cent.

Mr. L. COLLEDGE (London) considered that in acute cases it was safer and less likely to lead to recurrence of the disease to close the wound by secondary suture, and preferred to treat large bone cavities by the method of Carrel. After the radical operation he believed that the employment of Thiersch grafts not only led to quicker healing, but the end-result was better, also the hearing.

Mr. H. TILLEY (London) indicated how the dressings can be made painless when drainage-tubes are used by protecting the wound surface with pieces of oiled silk.

Prof. NEUMANN, in discussing the papers, gave statistics of 800 cases of acute mastoid disease, and demonstrated the surgical anatomy of the part in order to emphasise the importance of a complete primary operation.

Dr. SYME expressed himself an unrepentant advocate of bipp and primary suture.

In the afternoon a demonstration of otological cases was held.

FRIDAY, JULY 23RD.

THE NASAL SEPTUM.

Dr. JOBSON HORNE (London) read a paper entitled the Sorrows of the Septum. He said that the higher the type of race the more frequent was trouble with the septum. There was no hæmorrhage of greater frequency than bleeding from the nose, and no hæmorrhage that was sooner forgotten. Hence the difficulty in obtaining reliable statistics. He had found on inquiry that 142 people out of 1000 had recollection of blood dropping from the nose, obviously a low estimate. Nose-bleeding was rather more common in the male than in the female sex; and deformities of the nasal septum were also more common in the male sex. The bleeding-point in the vast majority of cases was to be found in the cartilaginous septum. The human face, in contrast with that of the lower animals, was characterised by being extended vertically instead of horizontally. This characteristic determined the development of the nasal septum, and the septum determined the development of the nose. The structures entering into the formation of the septum in man were subject to delayed or excessive development. The developmental activity continued not only up to puberty, but, in a greater or less degree, some years afterwards. With that activity there was an increase of newly formed blood-vessels, resulting in a greater tendency to epistaxis and to deformities of the septum. The higher the type of race, the more prolonged was the developmental activity and the more common the formation of ridges, spurs, and deflections. The vascularity of the septum was a cardinal point. It would be difficult to mention any condition of the septum that a rhinologist was called upon to treat that was not vascular in origin—for example, hæmatoma, abscess, fibro-angioma, bleeding polypus, septal thickening, outgrowths, ridges, spurs, crests, and last, but not least, deflections of the septum. Deformities of the septum were found in 80 per cent. of European skulls. Clinical experience taught that some irregularity of the cartilaginous portion of the septum was the rule rather than the exception. So that in the higher types of races the abnormal became the normal. Statistics based upon the examination of skulls of the lower types showed the reverse: the septum was free from deflections and irregularities in 80 per cent. In routine examinations of the nose one frequently met with ridges, spurs, and deformities of the septum in no way material to the case. The nasal symptoms complained of were often quite independent of any irregularity of the septum, and could be completely removed by other means without interference with the septum. Passing to the much smaller group of cases in which interference with the nasal septum was called for, Dr. Horne held that the operation for the removal of the septum by submucous resection was faulty inasmuch as it deprived the patient of a *rigid* septum, and thereby impaired the nose as an organ of respiration, and at times in other ways. The nasal passages after the operation at times were left too patent, the septum too thin, and patients complained of symptoms due to the flapping of the thin membranous septum in the passage of air. Further, in spite of a reduction of the anterior ends of the middle turbinated bodies at the time of the removal of the septum, very considerable hypertrophy of those structures had ensued in some cases, calling for relief from nasal obstruction. General anæsthesia for operations upon the upper air passages, particularly when prolonged, was attended with greater risk after interference with the septum. It was questionable whether the end-results of rectifying the nasal septum by removing it were any better than those obtained by other operations that left the septum intact. The procedure followed by the speaker when orthopædic surgery upon the septum was inevitable was a modification of Moure's operation. In spite of the argument about the resiliency of cartilage he claimed that the operation gave as good results without the unfortunate troubles that have followed submucous resection and removal of the septum. He was in favour of a limited submucous resection for the removal of spurs and ridges.

Dr. Horne's paper provoked an animated discussion, in which 14 members joined. Mr. TILLEY

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT NOTTINGHAM

(Continued from p 500)

SECTION OF LARYNGOLOGY AND OTOLOGY

Wednesday, July 21st.

Dr Brown Kelly (Glasgow) presided over this Section The first morning was devoted to a discussion on the treatment of

Malignant Disease of the Upper Air and Food Passages

Mr F J Steward (London) read the opening paper in which he dealt with the principles of surgical treatment He discussed the subject under four headings (1) Selection of Cases, (2) Preparation, (3) Operation, (4) After-treatment In selecting patients for operation it was convenient to divide them into three groups—favourable, doubtful, and hopeless Doubtful cases made up about 50 per cent of the total number seen, 40 per cent being practically hopeless when brought up, and less than 10 per cent being really favourable cases As to preparation, while recognising the extreme importance of oral sepsis, he was inclined to favour methods less drastic than those considered imperative by some operators in recent years, he recommended painting infected tonsils with 1 in 500 chinosol in glycerine In connexion with the operation, he advocated the use of the intratracheal insufflation of ether; he reviewed the methods of approach in various regions, emphasising the importance of repairing the wound as a definite third stage of the operation As to after-treatment, he recommended feeding by passing a soft rubber catheter obliquely through the wound in the neck into the pharynx The pharyngeal wall and skin should be fixed tightly round the catheter so that it does not slip out and there is no leakage

X Rays

Dr. Robert Knox (London) gave an account of the treatment by means of X rays in these regions where the small area containing a large number of structures makes it difficult to restrict the beam of rays accurately to the parts under treatment It was essential, further, that the skin and subjacent tissues should not be damaged, and the limited depth of tissue available presented another difficulty At the present time higher voltages enabled a greater intensity to be applied at a given depth, whilst working at a greater tube distance Filters on the skin of 2 to 10 cm of wax aided the operator in giving a strong dose at a depth with no risk of damage to the skin The exact technique applied on these principles was described by Dr Knox, and also the method of estimating the appropriate dose, which was usually given in fractions at short intervals The results, he said, had now greatly improved He recommended pre-operative treatment in cases complicated by wide-spread glandular involvement In inoperable cases X rays were used with no hope of cure but to alleviate symptoms, with a certain measure of success The outstanding feature in the improved technique had been the recognition that it was neither necessary nor advisable to adopt the lethal dose of Seitz and Wintz as the unit of effective dosage but to take this as a unit of measurement of the total dose, which would be spread over days, weeks or months according to the urgency of the case

Radium

Sir William Milligan (Manchester) discussed treatment by means of radium, and foreshadowed the time when, with improved technique and a more accurate knowledge of dosage and duration of exposure, radium would be used in operable as well as inoperable cases For the present his remarks were confined to the vast and distressing array of inoperable cases There were two schools (1) those who believe in large doses and short exposures and (2) those who believe in small doses and long exposures, to which latter Sir William Milligan himself belonged, the exposures being continued up to 10, 14, or even 21 days The conclusions which he had reached were as follows (1) that in the present state of our knowledge surgical removal of a malignant growth should be undertaken if a practical proposition, (2) that the lymphatic nodes into which the lymph stream from the growth drains should be removed by dissection or by block dissection, (3) that the lymphatic vessels between the growth and the infected nodes should be irradiated either from within or by external irradiation, preferably by the former method, (4) that the growth to be irradiated should, wherever possible, be exposed so as to admit of its being handled, (5) that the introduction into the growth of a large number of seeds containing small doses of emanation to be retained in situ gives even better results than the implantation of screened tubes; (6) that the introduction of the seeds should follow a definite mathematical plan, (7) that as the periphery of the growth is reached the emanation dose may be reduced, (8) that ligation of the main artery to the growth should invariably be carried out

Surgical Diathermy.

Dr. W S Syme (Glasgow) said that the value of surgical diathermy in the treatment of malignant disease of the mouth and throat decreased as the site of the disease descended from the alveolus to the œsophagus The most suitable cases were those confined to the mouth, including the tongue, jaws, palate, fauces and floor of mouth. Dental sepsis must be treated as for an ordinary operation As diathermy would not seal larger vessels, one or both lingual arteries or one or both external carotids might have to be ligatured A preliminary tracheotomy might be advisable Affected glands should be removed before or after the main operation In some cases glands which appeared to be inoperable become operable after the removal of the primary growth and the sepsis attendant on it In dealing with the growth itself the aim should be complete removal, first coagulating the tissue all round the tumour and then removing it, or its destruction in situ The former was the better method. In inoperable cases, however advanced, much relief followed surgical diathermy While diathermy caused remarkably little immediate shock, delayed shock could not be excluded, and experience taught that care must be exercised in regard to the duration of exposure to the diathermy current at one time Dr Syme gave statistics of 122 cases treated by this method during the four years 1922–25 Of these 39 were alive on May 31st, 1926, varying from over six months to over four years after operation, 13 having survived for more than three years without recurrence He claimed that in the treatment of malignant disease of the mouth the method of removal by diathermy was preferable to any other

In the discussion which followed these four papers a large number of visitors took part, including Dr William Hill (London), who gave a demonstration of the technique of applying radium in the treatment of œsophageal cancer, and Prof H Neumann (Vienna) who spoke of the use of intravenous injections of sugar as an auxiliary to X ray treatment

In the afternoon Mr A R Tweedie and Mr Bell Tawse showed laryngological cases, including many which had been successfully treated by operation for malignant disease These patients amongst whom was a man with an unusually large pharyngeal pouch formed the basis of a discussion

Thursday, July 22nd

The second morning was spent in a discussion on the

After-Treatment and Results of Mastoid Operations

Mr Norman Patterson (London) presiding The opening papers by Mr G J Jenkins (London) and Mr J S Fraser (Edinburgh) dealt respectively with operations for acute disease and with the radical mastoid operation lying constitutional factor, which undoubtedly had a bearing on the ætiology. It was in this category that we should place those cases which appear to depend on focal sepsis for their origin, and may clear up permanently when the foci have been discovered and eliminated.

In summarising his conclusions Dr. Whitfield stressed the following three points: (1) Eczema is a clinical condition and not a disease with a single specific cause. (2) It is the result of irritation of the skin, and is associated with an undue susceptibility. (3) This susceptibility may be congenital or acquired, and when acquired may be the result of repeated external trauma or a generalised toxæmia of particular type.

Dr. W. Dyson (Manchester) defined eczema as a non-microbic affection of the skin, produced by external irritation, in a predisposed subject. The predisposition, which implied an abnormal susceptibility to physiological stimuli of all kinds, once acquired, might remain local in a single area, or might spread and become more or less generalised. The stimulus which caused the reaction might be a single specific one at first. Later, specificity might be lost, and the patient's skin respond to all and any variety of what in normal individuals were regarded as the ordinary physiological stimuli of daily life—e.g., light, heat, water, &c.

Dr. Dyson made the further suggestion that the skin itself might occupy in the normal economy a position in some degree resembling that of the ductless glands. The anatomical and microscopic structures did not altogether differ in certain respects. He thought that the therapeutic action of X rays might be to some degree explained by such an assumption. Their action might set free certain substances which, finding their way into the circulation, might there give rise to the production of specific antibodies, which in their turn would have a favourable action on the course of the disease.

Dr. H. W. Barber (London) was in almost complete agreement with the observations of Dr. Whitfield. He proposed not to discuss the ætiology of eczema in general, but to attempt to differentiate certain clinical types of the eruption with a view to seeing whether it is not possible to deduce the probable cause in a given case from the distribution, configuration, and type of lesion present.

As regards "seborrhœic eczema," he agreed that this was not a true eczema, but an inflammatory reaction of the eczematous type (eczematide of Darier) due to infective organisms, comparable to that produced by a ringworm fungus. But occasionally in seborrhœic patients—particularly in hot weather—an acute true amicrobial eczematous reaction did occur—for example, on the hands and feet. This might be comparable to the third type of "seborrhœic eczema," referred to by Dr. Whitfield as occurring on the back, which he has suggested may be due to irritation by a fatty acid—e.g., butyric acid—produced by bacterial decomposition of sweat. But such an eczema—at any rate when it occurs on the palms and soles—was more likely, in the speaker's opinion, to be due to the actual excretion of fatty acids by the sweat glands, as the palmar sweat is always strongly acid in these cases, although sebaceous glands are absent on the palms and soles. This type of eczema might occur in seborrhœic subjects, apart from any active seborrhœic dermatitis being present. The condition labelled "infective eczematoid dermatitis" by American authors had been shown to be a definite entity due to epidermal sensitisation to a staphylococcus. "Nummular eczema" was characterised by bilateral symmetry of the lesions, the eruption occurring chiefly on the limbs. The primary lesion was often a single eczematous papule which became a vesicle of considerable size, drying up to form a single brownish scab. The nummular patches were more or less circular with sharply defined margins, and were characterised by the relatively large size of the vesicles and resulting scabs and their tendency to remain discrete. The evolution of this type of eczema made it almost certain that the toxin to which the epidermis was sensitised was borne in the blood-stream whether from a focus in the skin itself or from within. True gouty eczema was in these days rare, and should not be diagnosed unless associated with a high blood pressure and abnormal uric acid blood content. There was the type of eczema occurring in patients who had inherited the ichthyosis-asthma-hay-fever-prurigo-eczema-urticaria complex. They had almost invariably suffered from infantile eczema, and later developed circumscribed prurigo. The majority were, perhaps, ichthyotics, but apart from this their skin was curiously sallow, thickened and œdematous looking, so that they could be recognised at a glance.

Dr. A. R. Hallam (Sheffield) questioned the necessity of external causation in the production of eczema, and believed in the possibility of its occurrence without it. He quoted the experiments of Jaeger (a pupil of Bloch), who applied plasters containing known percentages of certain irritants to a large number of individuals, of whom a proportion were known to be eczematous subjects. Of these 35 per cent. gave a positive reaction in the specific eczematous sense, of the remainder only 5 per cent., and these had therefore to be regarded as potentially inclined to the disease.

Dr. Haldin Davis (London) declared that more research into the internal chemical mechanisms of the body was necessary before an advance in our knowledge of the ætiology of eczema could be made. He had found that some cases could be benefited by the exclusion of sugar in the dietary, and in view of this fact had tested the blood-sugar reactions of some 50 eczematous patients at the Royal Free Hospital. An abnormality in one of three directions was detected in two-thirds of the cases examined. Eczematous subjects appeared to show either (1) a high resting value, or (2) a higher rise after glucose ingestion than is normal, or (3) a slower fall. He thought the nervous system might well be implicated in causation, and suggested that, just as in tetanus, the toxins responsible might travel and distribute themselves by way of the perineural sheaths.

Dr. H. Semon (London), while admitting the accessory importance of blood states such as hyperglycæmia and gout, and local traumatism in trade or varicose dermatitis in the causation of eczema, could not subscribe to the view that these factors alone or combined were sufficient to produce the classical eruption in subjects who were not predisposed to it. In his view it was necessary to assume the existence of a specialised cutaneous response, which an American author had concisely termed a "tissue idiosyncrasy." Dr. Semon suggested that in view of the fact that skin areas occupied by nævi never showed any reaction when the whole of the rest of the body might be involved in the eczematous response, the actual anatomical structures reacting might conceivably be the vasoconstrictor and dilator nerves, which were known to be altogether lacking in neurovascular structures.

Dr. G. B. Dowling (London) drew a nosological distinction between eczema and dermatitis, and suggested that the latter term should be retained for that form of skin reaction which was evoked by the irritation of industrial chemicals—e.g., soap or other recognised skin irritant. He thought that constitutional factors must be multiple, and might be congenital or acquired. In the present state of our knowledge it was impossible to recognise or even define the nature of the primary sensitising substances. Some of them might well be produced by autolysis of skin or other tissue. He quoted a recent case of his own in support of the suggestion, in which the patient, who suffered from lupus vulgaris of the face, was treated by pyotropin—a local caustic containing salicylic acid and potassium phenolate. After the second or third application a ring of minute eczematous vesicles appeared round the treated and Mr E B WAGGETT making useful suggestions as to the causes of the failure of operations on the septum to give benefit or relief in certain cases

Dr. WILLIAM HILL followed with a paper on

PHARYNGEAL AND ŒSOPHAGEAL DIVERTICULA

He gave a historical account of the subject, and illustrated his address by a large number of pictures and X ray photographs He advised the pathological classification of diverticula as follows:—

Solitary Diverticula of Upper Food Tract

I —*Pharyngeal in Origin*

A *Congenital*
1 Anterior median branchial diverticular sinuses and pouches (Rare)
2 Lateral branchial diverticular sinuses and pouches (Rare)

B *Acquired*
3 Deep postero-median pulsion pouches (*Not rare*)

II —*Œsophageal in Origin*

B *Acquired*
4 Traction pouches of Rokitansky (Not rare)
5 Leugart's post-branchial ledge pouches
6 True pulsion pouches (Usually low down but above level of diaphragm—the epi-phrenic of Starck) (Rare)
7 Pulsion-traction pouches of Starck (Rare)

Boundary cases at the pharyngo-œsophageal junction, he stated, do not exist

Dr E I SPRIGGS (Ruthin) gave a detailed record of two cases under his care They had been long under observation, and had been treated without resort to surgical interference Dr Spriggs pointed out the analogy between pharyngeal and duodenal diverticula, of which he had met 43 in a series of 1000 examinations for disease of the duodenum

Mr L COLLEDGE, on behalf of Sir StClair Thomson, indicated the difficulty of classifying pharyngeal diverticula as the symptoms were œsophageal, therefore in a pathological classification they should be included under diseases of the pharynx, but in a clinical or symptomatic classification they came under diseases of the œsophagus

Dr W. H KELSON related the subsequent history of two patients successfully treated by operation one of these had died from bronchitis, and the other from malignant disease arising in the scar.

The PRESIDENT, speaking from an experience of 17 cases, had noticed that dysphagia is not an invariable symptom, as some patients only complain of hawking and " phlegm in the throat "

Mr DOUGLAS GUTHRIE (Edinburgh) read a paper based on 20 cases of

ACUTE RETROPHARYNGEAL ABSCESS IN CHILDHOOD

He said that acute retropharyngeal abscess in the majority of instances was due to suppuration in lymphatic glands, sometimes of tuberculous nature, but more frequently streptococcal. The tonsil was the original source of infection in many cases Injury during removal of adenoids was a possible cause, as also the direct spread of pus from the middle ear The majority of patients were under 1 year old, and the disease was commoner in boys than in girls The condition was very rare in adults Difficulty of breathing was the leading symptom This might suggest laryngeal diphtheria and might even lead to the fatal mistake of performing tracheotomy The larynx in the infant was relatively small, and was situated at a higher level than in later life, so that laryngeal obstruction was usually caused by the abscess, which tended to point just opposite the upper aperture of the pharynx Difficulty of swallowing was a rare symptom and the characteristic throaty cry, so often described, was seldom heard Diagnosis was merely conjecture until the throat was examined Even then it might be difficult to appreciate by inspection alone the altered contour of the posterior pharyngeal wall on one side Digital examination was the most certain test, but should not be practised without preparation to open the abscess immediately. The condition was often confused with adenoids, and laryngeal diphtheria or a foreign body in the œsophagus might be suspected Lymphosarcoma might simulate abscess, but was much rarer. Cervical scoliosis caused a unilateral projection of the posterior pharyngeal wall of bony hardness As soon as retropharyngeal abscess had been diagnosed it should be opened If left to itself it would cause death from suffocation, or, should the patient survive this contingency, from bronchopneumonia In the author's series of 20 cases two survived after spontaneous rupture of the sac External operation should be reserved for the chronic variety due to bone tuberculosis No anæsthetic should ever be given as it increased the risk enormously The child should lie on his side firmly fixed in a blanket A gag was then inserted, and the point of a long sinus forceps plunged into the most prominent part of the swelling and opened in a vertical direction At the moment of opening the child was turned on his face Pus flowed from the mouth and nose and relief was immediate Mr Guthrie believed that fatalities during the operation would be largely avoided if this method were adopted In the series of 20 cases described death occurred in three. Two of these died on the way to hospital, and the third just after the abscess had been opened.

SECTION OF DERMATOLOGY

FRIDAY, JULY 23RD.

Dr H G. ADAMSON (London) presided over the deliberations of this Section The first subject under discussion was

ECZEMA.

Dr A WHITFIELD (London), who gave the opening address, recalled Willan's definition of the eruption—" a sheet of minute vesicles, with no tendency to enlarge, not inflammatory in origin, or appearance, and not accompanied by fever—a *condition* rather than a disease, and one which might be called forth by a variety of causes " Dr Whitfield pointed out that the histological appearances invariably coincided with the clinical manifestations There is congestion of the capillary loops at the heads of the papillæ, subsequent exudation of lymph, distension of the intercellular channels (spongiosis), and a more or less rapid spread of fluid upwards through the rete mucosum until a deep-seated vesicle is apparent to the naked eye It followed that if the exudation be checked at any stage a papule and not a vesicle may be the final result Eczema therefore consists of vesicles or papules. other forms of dermatitis—e g , pyogenic, marginated, &c —which are not constituted by these fundamental elements have no right to the name Culturally, eczema vesicles were always sterile in their incipience but secondary infections from skin saprophytes were the rule In attempting to define the nature of the stimulus responsible for the exudation Jadassohn classified eczematous skins under two heads (1) those reacting to very small doses of a particular irritant, or a general susceptibility to a number of such. and (2) those which react to substances which in respect to normal skins could hardly be classed as irritants at all Hence, in eczema there is an irritability special or general, which we may term a susceptibility. It may appear soon after birth or may be acquired later

The Constitutional Factor

Dr Whitfield referred to the type of eczema of the arms, neck and face, which is not infrequently seen as a secondary manifestation due to the sudden irritation and " flare up " of a chronic patch of varicose dermatitis on the leg *This may be quite* indistinguishable from ordinary *eczema, and will* clear up without particular *attention if the leg* patch is treated and brought under *control* Another type of eczema, in Willan's *sense*, and one which may alternate with urticaria *from* food poisoning, is a follicular dermatitis of the *trunk* and extremities mainly In both these examples there was an under-doses. He had had some therapeutic success with a polyvalent staphylococcal vaccine but had now given it up for curative purposes. He was under the impression (40–50 cases tried) that this vaccine was useful in preventing recurrences. He quoted a nurse who had apparently been saved from relapses by its use for over two years although previously never free, after renewal of the eruption, for more than six to eight weeks. He had had success with a Danysz vaccine in one or two cases but he agreed that the results were most uncertain and could never be foreseen.

Dr. **BARBER** thought ultra-violet light in some cases did more harm than good. He advocated concerted action among British dermatologists to determine the cause of psoriasis, and alluded to the frequency of tonsillitis as a precedent to the eruption, especially in rheumatoid cases. In conjunction with Dr. D. Embleton he had found an organism of the streptococcus group in some cases of psoriasis associated with rheumatic symptoms in the joints. In one of these, a very severe case which had gone on to generalised exfoliative dermatitis with high pyrexia, it had been recovered from the blood and cultured. The autogenous vaccine injected immediately checked the fever, and may have been partly responsible for an ensuing cellulitis of the thigh, from which the same organism was cultivated. The patient eventually recovered. Dr. Barber admitted that the cases were at present too few for him to draw any conclusions as to the ætiological importance of a bacteriological cause of psoriasis.

Dr. E. F. **SKINNER** (Sheffield) said he had made an experimental clinical investigation of the comparative value of chrysarobin and X rays in the treatment of psoriasis. In two selected groups, in which dietetic and other factors remained the same, he was able to demonstrate the definite superiority of the chrysarobin method, both in the rapidity of involution of the individual lesions and in the prolongation of the immunity intervals. The average duration of treatment in hospital by this method was from 20–30 days. In the group selected for radiotherapy one-third of a unit dose was given to each patch. Dr. Skinner showed some slides illustrating both the clinical and microscopic results of treatment. His investigations had led him to believe that a diminished intradermal pressure with increased oxygen tension were invariable associations of the psoriatic lesion. He was not much impressed with the results of ultra-violet ray treatment in psoriasis.

Sir **NORMAN WALKER** emphasised the fact that there is no generally applicable treatment for psoriasis. Every case had to be treated individually, and long experience was the only safe guide. He entirely agreed with Dr. Skinner in his estimate of the value of chrysarobin. In connexion with tar applications it should be remembered that there were various tars—some derived from coal, some from pitch-pine—and that they were not all suitable in every case of psoriasis. While there was no remedy which could be relied upon as a specific, Sir Norman Walker protested against the practice of giving a bad prognosis. The policy of laissez faire was bad, and the patients must be encouraged to use the best possible means to rid themselves of every ensuing attack.

Dr. **WHITFIELD** said that he would exercise extreme caution in prescribing arsenic to acute or irritable cases, and in those non-scaly glazed types which were by no means uncommon. He said that when he prescribed arsenic he found it did most good when pushed to the limit of tolerance.

In his reply Dr. **MACKENNA** expressed himself as much interested in Dr. Dyson's remarks on the preventive effect of treatment by vaccines. He thought that his views, perhaps too optimistic on the results of phototherapy, might have been due to the fact that the majority of his cases were treated in the winter months, at a time when sunlight was deficient.

Reviews and Notices of Books.

CHRONIC RHEUMATIC DISEASES

Their Diagnosis and Treatment. By F. G. THOMSON, M.D., F.R.C.P. Lond., and R. G. GORDON, M.D., D.Sc., M.R.C.P. Edin. Oxford Medical Publications. London: Humphrey Milford, Oxford University Press. 1926. Pp. 202. 8s. 6d.

THE appearance of this book is well timed, following the report of the Ministry of Health on rheumatic diseases, in which it was shown that about one-sixth of the total amount of sickness occurring amongst the insured population is due to diseases in this group, and that every seven insured persons cost the insurance funds £1 per annum in respect of these diseases—a total of £2,000,000 per annum amongst our insured people alone. However, students still can and do graduate from our large hospitals with little knowledge of chronic rheumatism beyond the fact that it is a disease prevalent amongst out-patients, and is usually treated with salicylates internally and liniment as a placebo. The authors of this handy volume do not claim to describe any hitherto unpublished original research; none the less, its study will give information which will be new to many.

The book is divided into three parts. The first deals briefly with ætiology, and then describes the clinical types showing clearly how they differ or overlap. The following reason is given for dropping the name "rheumatoid arthritis" and substituting "focal arthritis": "The name 'rheumatoid arthritis' conveys no suggestion of the main ætiological factor, and may even mislead by suggesting a false relationship to rheumatic fever. On the other hand, the term 'focal arthritis' not only emphasises the underlying cause, but serves as an emphatic reminder to the medical attendant that it is his duty to find out where the infection lies, and to treat it thoroughly and effectively at the earliest possible moment." The nomenclature throughout is simple, and the reader cannot fail to grasp exactly what the authors mean. The clinical descriptions of fibrositis, neuritis, lumbago, the various forms of arthritis and gout are all good. The 24 pages which comprise Part II. deal with common mistakes in diagnosis. Read in conjunction with the clinical descriptions in Part I., they cover the ground thoroughly and supply a reminder that routine physical examination is necessary even of the patient who makes no more than a casual complaint of a touch of rheumatism. Neglect of this precaution may bring serious trouble to doctor and patient alike. Treatment is described in Part III. under the headings drug treatment, hydrology, climate, physiotherapy, orthopædic treatment, vaccines, and diet. It would appear that the authors have not seen the ill-effects from the use of drugs of the atophan group described by other clinicians, otherwise these dangers might have been more stressed. There is a short paragraph summarising the points to be considered by the doctor who is debating whether or not to send his patient to a watering-place. The information under the headings physiotherapy and orthopædic treatment will be quite as useful to the general practitioner as that concerning drug treatment. Not only is it emphasised that joints must be kept in the position of optimum efficiency during acute inflammation, but it is shown how this may be done.

A doctor who has had the depressing experience of seeing a patient become crippled and deformed in spite of his efforts will appreciate the value of the teachings though even with the knowledge they impart treatment is difficult enough. No enthusiasm is shown for vaccine therapy; protein shock is regarded as still sub judice, but without much promise. The fact that this book is written by two spa physicians has some significance. Although our large mineral water areas and gradually spread until a typical eczema of the face and neck had developed

Sir **Norman Walker** (Edinburgh) noted that only one mention of gout as a causative factor (that by Dr. Barber) had been made on this occasion, and said that in 1892 at a B M A meeting the diathesis had completely dominated the discussion He thought that everybody must now be convinced of the importance of focal sepsis in causation Again and again the removal of such a focus had resulted in cure or alleviation of the skin condition He entirely agreed with Dr. Whitfield's picture of the chronic patch of varicose dermatitis lighted into activity by the application of a strong and unsuitable dressing, and directly responsible for an eczematous outbreak in other parts of the body With regard to seborrhœic eczema he desired to apologise for the word *Bottle* bacillus, for which as translator of Unna's original paper he must take the responsibility *Flask* bacillus was the correct translation Sir Norman Walker was convinced of the considerable importance of internal factors in the causation of eczema, and stated that cutaneous protein tests had been of some use in elucidating them in one or two of his own cases. He was very much in favour of a biochemical training for the future dermatologist, and believed that this offered the best prospect of advance in the science In conclusion, he uttered a serious warning against the indiscriminate use of X rays in treatment

The **President** congratulated Dr Whitfield on the able way in which he had summarised the present state of our knowledge of the causation of eczema, and expressed agreement with the essential definitions and conclusions suggested in his paper For his own part he had never been able to convince himself that internal causes had anything to do with the problem of eczema, and in support of that view he instanced the effect—almost invariably successful in his hands—of local treatment in the control of infantile eczema—the purest of all types of the condition, and one in which an almost complete protection against both physiological and abnormal stimuli could be ensured.

In his reply Dr **Whitfield** stated that in his view eczema could be either a congenital susceptibility or acquired by the effect of repeated trauma He felt convinced that an external stimulus was of prime importance in the production of the eruption, and instanced in support of that contention the effect of light on the exposed parts—face, neck, and hands—of such patients He agreed that gouty eczema was a very rare condition, and stated that in the whole course of his experience he had seen not more than 100 cases. He cordially agreed with Sir Norman Walker's warning on the subject of radiotherapy It had become his practice to record the areas irradiated, and the doses on charts which he gave to all private patients, so that in the event of further treatment by others the charts were available for reference, and due precautions could be exercised.

The Treatment of Psoriasis

A discussion on this subject was opened by Dr **Robert W MacKenna** (Liverpool) He said that since there was still complete ignorance of the cause of this common disease the treatment must be appropriate to the stage and character of the lesion in any individual case. In the acute stages, with new lesions rapidly appearing and developing, the patient should be put to bed, on a light diet, regular purgation, &c. Antimonial wine (7–10 minims t d s) a valuable remedy for acute skin conditions, and too often forgotten, might prove very beneficial, and could do no harm. The speaker had had no success with emetine injections, while arsenobenzol derivatives, administered intravenously, and injections of whole blood (auto-hæmatotherapy) had also proved disappointing in his hands Mixed coli vaccine in no instance produced involution by its own unaided effect, but in cases which had indicanuria it seemed to have an adjuvant effect in accelerating recovery A striking example of the outcome of "protein shock" therapy was provided by a nurse under Dr. MacKenna's care in 1922 She had had intermittent psoriasis for 12 years, and this attack was so severe and generalised that she was put to bed and treated as for a severe exanthem A week later an abscess developed in the axilla, and as this grew and "ripened" the skin lesions faded, pari passu Dr. MacKenna said that this concomitant septic infection was recognised as a useful ally, he was in no hurry to open the abscess prematurely The patient did not have another outbreak of psoriasis for 15 months Imitating this natural form of "fixation abscess" Dr MacKenna had tried the effect of intramuscular injections of terpichin, an oily compound of purified turpentine and quinine, in doses of 1 c cm once or twice weekly It appeared to quieten the period of acute development and accelerate involution, but in no case did it do this unaided by local treatment Sulphur colloidal solutions by the mouth were useful, also intramine given intramuscularly, 0 75–1 5 c cm weekly, but as with the other injections local treatment had always to be invoked

Of local treatments X rays appeared to be the most valuable and rapid, but they had the obvious drawback that only a limited number of areas could be irradiated , also that tolerance to X rays might be easily exceeded, and a burn might result if more than one or two doses were given It ought not to be applied in acute cases, but only to the chronic patch The drawbacks applying to X rays were absent in connexion with ultra-violet radiations which could be given safely and frequently to the whole body A successful case was cited in which a series of exposures to an air-cooled mercury-vapour lamp had banished an inveterate eruption in a woman with a 27 years' history

As regards *diet* nothing definite could be laid down It had been found that 20 per cent of psoriasis cases gave evidence of putrefaction in the bowel and 26 per cent of carbohydrate fermentation Free purgation, assisted if necessary by high irrigation, seemed to be indicated in such cases, and excess both of carbohydrate and protein in the diet should be avoided Salicin was admittedly a valuable drug in acute and spreading cases (10–15 gr t d.s), and iodide of potassium had sometimes proved efficacious Glandular extracts were very disappointing In local applications it was important to begin with weak concentrations of any drug chosen, and gradually increase when the tolerance had been ascertained By far the most effective was chrysarobin, while equal parts of tar, glycerole of lead, salicylic and mercury ointments was an extremely serviceable and harmless application when properly used The combination had a rational basis, for tar and mercury were reducing agents, salicylic acid keratolytic, and the glycerole of lead hygroscopic and soothing The tenacity and adhesive properties of the mixture rendered it valuable for firm inunction and massage, which in itself appeared to do good in the œdematous type of case The actual percentage of the various drugs incorporated depended on the stage of the eruption If acute and spreading rapidly it would be wise to employ weak concentrations, particularly of the tar ointment The only one of the remedies cited that could be relied upon to cause the eruption to disappear "with precision and promptitude" was chrysarobin, and recurrences after its use were just as frequent as with other remedies The problem would not be solved until the physiologists and biochemists were able to reveal some of the more intricate processes of cell metabolism

Dr **Dyson** emphasised the importance of rest in bed in acute or intractable cases In his experience salicin was valuable in the acute stage, arsenic in the chronic Excessive tar inunction often led to follicular infection, and he was in agreement with Dr MacKenna in his warning against using chrysarobin in acute cases Pyrogallic acid was useful for chronic patches Dr Dyson had only seen benefit from thyroid when the patient was made ill by excessive views of one who has been associated with work on insulin from its beginning The volume is certainly not a complete summary of the literature on this subject as many important researches by European workers are omitted, yet as Prof Macleod states, "if undue weight may appear to be given to the work which has gone on under my own supervision, it is hoped that this will be pardoned on the ground that otherwise it would have been impossible for me to prepare the monograph "

DISORDERS OF NUTRITION AND GROWTH IN CHILDREN

Clinique Médicale des Enfants Troubles de la Nutrition et de la Croissance By P NOBÉCOURT, Professeur de Clinique Médicale des Enfants à la Faculté de Médecine de Paris Paris. Masson et Cie 1926 Pp 404 Fr 36

THE third volume of Prof. Nobécourt's notable system of children's diseases is on the same lines as its predecessors, detailed clinical accounts of individual patients being followed by a discussion of the conditions which they exemplify This volume is perhaps the most attractive of the series

The first part of the book is devoted mainly to the different types of hypotrophy in children, the cases described are illustrated by excellent photographs and by radiograms of the hand and carpus, the development of ossification centres being taken as one of the most useful points of distinction between the different types of retarded growth The varying degrees of hypothyroidism, and the effect of syphilis in diminishing growth, are fully discussed in their relation to hypotrophy The question of statural hypertrophy is approached in the same way, with special reference to the rôle of the endocrine organs The author recognises three main types the Hutinel type with delayed puberty and a subsequent stature not greatly in excess of the normal, acromegaly, and hypertrophy of stature with precocious puberty The cases of obesity which Prof Nobécourt describes are of remarkable interest, as is his discussion of the problem of their pathogenesis He is convinced that many cases of obesity in children are wrongly attributed to diminution of pituitary secretion, and are of cerebral origin; when found in association with a pituitary tumour they are the result of neural lesions caused by pressure on the tuber cinereum or surrounding parts of the brain This view is supported by evidence which he brings forward of obesity occurring as a sequela of encephalitis, also resulting from lesions of this locality A few chapters are devoted to the clinical features and treatment of diabetes; some of these were written before and some after the introduction of insulin treatment Non-diabetic acetonæmias are also discussed, and attention is drawn to the meningeal reaction which may accompany them, and the alterations which they produce in the cerebro-spinal fluid

This volume further establishes Prof Nobécourt's "Clinique Médicale" as one of the most important works on pædiatrics, and will give both pleasure and instruction to all who are interested in problems of growth and of endocrine function

NEMATODE WORMS

A Synopsis of the Families and Genera of Nematoda By H A. BAYLIS and R DAUBNEY London Trustees of the British Museum. 1926. Pp xxxvi. + 277. 10s 6d

ZOOLOGY is essentially a science of classification, and this is no less true for the more economic branches than for the purely scientific Without classification we are unable to apply effectively our knowledge of biology and preventive measures, and although to the true biologist the name of an animal is merely a label, without a systematic knowledge of these names chaos would result This is particularly true of the round worms, over 600 genera of which are described and classified in the present work It is unfortunate that the authors have stopped at genera, as the absence of species considerably reduces the value of the book to the general zoologist and the medical man A genus is often an artificial collection of species based on some arbitrarily chosen morphological detail; and while the authors on the whole have avoided the obvious pitfall they have often been compelled to write a diagnosis of a genus containing a single species —a task of great delicacy and sometimes questionable value as such a species is often proposed on account of its differences from other genera rather than on its own intrinsic characters

The classification of the "worms" has received a great amount of attention in recent years, but in most cases only the parasitic forms have been considered Baylis and Daubney believe, however, that a more accurate system should include all nematodes, free-living or parasitic, without regard to their habitat The adoption of this plan has in their hands led to some curious anomalies although there can be no doubt that it gives a sense of perspective to the study of the purely parasitic forms and a sense of perspective is a valuable adjunct in all the branches of economic biology

As the last word has yet to be written on systematic helminthology, few students of the nematodes will agree with everything in this volume, but many will agree with most, and all will welcome the addition of such a concise synopsis to their library shelves

PUBLIC HEALTH ENGINEERING

The Principles of Public Health Engineering By EARLE B PHELPS, B S Professor of Sanitary Science, College of Physicians and Surgeons, Columbia University New York: The Macmillan Company 1925 Pp 265 12s 6d

THIS book in spite of a title not particularly attractive to medical men, will be found to make interesting reading It is intended for the health officer with little knowledge of engineering and for the sanitary engineer whose understanding of the public health objective of his efforts is usually vague The author, a chemical biologist who has become a sanitarian is well equipped for his task. The scope of the work is limited to a few problems—viz ventilation and atmospheric pollution, water-supplies, sewerage, pasteurisation, lighting, refuse disposal, and insect control In each of these subjects the fundamental principles involved and their application to the needs of society, are discussed in relation to modern scientific investigation and engineering practice The treatment is perhaps more satisfactory on the scientific than on the practical side, but even practical issues are dealt with more thoroughly than is customary in the ordinary text-book on public health Interest is enhanced by the exposition of the results of investigations by the author and other workers on sanitation in America, which compensate for the somewhat astonishing meagreness of the references to English and other European observers in a branch of medicine which we have been accustomed to regard as peculiarly our own

This book should be read by every medical officer of health and teacher of hygiene, and it may also be recommended to civil engineers whose work brings them into contact with problems of sanitation

JOURNALS

QUARTERLY JOURNAL OF MEDICINE —The July number contains the following articles: The Effect on Renal Efficiency of Lowering the Blood Pressure in Cases of High Blood Pressure, by Charles Reid. Certain renal efficiency tests, such as the estimation of blood-urea and non-protein nitrogen and the urea-concentration test, were made upon patients suffering hospitals do not confine themselves to the treatment of rheumatic diseases, patients suffering from these diseases form the majority of their cases, and, as the urgent routine work of pathological and biochemical departments is less than that of general hospitals, it is to spa institutions that we may look for further advances in our knowledge of these economically disastrous diseases This book contains all essential information concerning its subject and has no padding It is light to hold, and is well produced

MEDICAL DIAGNOSIS

Sixth edition By CHARLES LYMAN GREENE, M D, formerly Professor of Medicine and Chief of Medical Clinic, University of Minnesota, Chief of Staff, St Luke's Hospital London William Heinemann. 1926 Pp 1468 £3 3*s*

THIS costly and richly illustrated volume should prove attractive to the studious medical man who wishes to possess a work on general medicine which escapes from the usual format of text-books Dr Lyman Greene is well qualified to produce such a work, both by a wide experience and a clear style of writing After sections dealing with fundamental principles and case-taking he discusses in detail the methods of investigating and the clinical features of diseases of each system of the body. If there is a major criticism to be made, it is that the space devoted to the cardiovascular system is disproportionate to that given to other parts of the body This portion of the book is filled with accurate observations and readable descriptions, and the author has expressed his personal views with a fearlessness which must commend itself to critics But the general reader may yet be disappointed at the relatively small amount of space devoted to other important sections, notably to diseases of the lungs and to abdominal diseases As is always the case with books of this magnitude, the laboratory methods, sometimes described in great detail, may be out of date by the time they reach the reader; thus page 999 contains full description of the original Rosenthal test for hepatic efficiency, the method is here placed alone under the heading Determination of Liver Function, whilst a footnote only refers to the method which has since completely supplanted the one described Still more surprising to English readers will be the omission of reference to the van den Bergh test or to cholecystography, whilst many less important methods of examination are prominently recorded. But such omissions are inevitable in a production of this size by one observer, and we are well content to ignore them in a work which carries such a strong individual message.

ORTHOPÆDIC SURGERY.

By W A COCHRANE, M B, Ch B, F R C S Edin, Assistant Surgeon, Edinburgh Royal Infirmary, late Clinical Assistant, Orthopædic Department, Massachusetts General Hospital, Boston, U S A 1926 Edinburgh E and S Livingstone Pp 528 21s

THIS book, written by an Edinburgh surgeon, is largely inspired from American sources, and gives prominence to views and lines of treatment to which little attention has been paid in this country hitherto

Following the lead of Joel E Goldthwait, a school has arisen in the United States which attributes much more importance to the effects of posture than has been admitted elsewhere. Whether or no bad carriage of the body is more a cause than a result of abnormality, it is time that the profession in Great Britain should have the arguments in favour of Dr Goldthwait's conclusions adequately put before them These Mr Cochrane has well presented in Part I, which includes also chapters on physical education and reconstruction The rest of the book deals, by means of a regional and not an ætiological classification, with disabilities and affections which Mr Cochrane includes under the six heads into which he has divided the surgery of the locomotory apparatus, a title hardly comprehensive enough to cover all the domain Beginning with the feet and ankles, the author takes his readers to the knee, hip, spine and thorax, shoulder, elbow, and hand and wrist, to reach in the final chapter torticollis, acute anterior poliomyelitis, and spastic paralysis. Fractures in the neighbourhood of joints, such, for instance, as those of Colles and Pott, receive attention, but for information about fractures in general the reader must turn elsewhere and then could not do better than consult the joint work on Fractures and Dislocations of Wilson and Cochrane, published in 1925 Trauma and disease of the sacro iliac joints are conditions to which much more attention is paid in certain schools of surgical thought in America than in Europe Such injuries must be much commoner in New England than here, or else their occurrence is here overlooked Mr Cochrane gives a good description of the symptoms and morbid appearances on which American surgeons rely, and his account of this subject should arouse attention to these conditions in Great Britain

This book is well printed and illustrated, and it offers in a handy form a useful guide for practitioners in the treatment of orthopædic cases

CARBOHYDRATE METABOLISM AND INSULIN

Monographs on Physiology By JOHN JAMES RICKARD MACLEOD, F R S, M B, LL D Aberd, D Sc (Hon), Professor of Physiology, University of Toronto, Canada London Longmans, Green and Co 1926 Pp 357 18*s*

THE monograph under consideration deals mainly with the physiological aspect of insulin Prof Macleod sets out to prove that insulin is derived from the islets of Langerhans, and commences the monograph with a detailed account of the histology of the islets, and a very interesting summary of the comparative anatomy of these structures This part of the text is illustrated with photomicrographs, some of which are very clear, but others are of rather doubtful value For instance, it is difficult to imagine what Fig 4 is meant to illustrate Prof Macleod points out that by far the greatest yield of insulin is obtained from the islets, and, although he refers to the observations of other investigators who have shown that insulin can also be obtained from the acinar tissues, he does not consider that this weakens his argument There is no reference to the observations which describe the presence of insulin in the tissues of depancreatised dogs, nor to the discovery of insulin in large quantities in tissues other than the pancreas These observations are very difficult to explain if the classical theory as to the action of insulin be adopted It must, of course, be borne in mind that "no other organ or tissue can replace the pancreas as the source of this hormone in the animal body"

There is a very brief description of the main methods for the preparation of insulin, together with a short account of its chemical properties Then follows a detailed account of the metabolism of the depancreatised dog treated by dietetic means and with insulin This ground is very familiar, and many reports on the subject have been published, but it is interesting to read the views of one of the original investigators on the question, and these are summed up in one of the later chapters The mechanism of the action of insulin is discussed at some length, but this subject is, of course, an unsatisfactory one, and up to the present no definite statement as to the action of insulin can be made The final chapter deals with methods of assay, and consists mainly of a summary of the recent publications of the Standardisation Committee of the Health Section of the League of Nations

This monograph is of great value in that it gives the general reader an opportunity of hearing the

For Invalids and Convalescents

HORLICK'S MALTED MILK presents the Proteids and Carbo-hydrates of Cereals and Milk in the proper ratio which affords a maximum of nutrition with a minimum tax on digestive effort It materially assists the building-up processes by making good the wastage entailed by illness, accelerates the recuperation of the digestive and assimilative powers, thereby preparing the way to a resumption of a solid diet. Complete in itself and ready in a moment by briskly stirring the powder in hot or cold water only

To secure the original, always specify HORLICK'S.

from increased blood pressure both with and without renal disease, before and after the application of measures designed to cause a temporary lowering of the blood pressure The investigations were undertaken in order to determine whether the efficiency of the kidneys is affected by lowering hypertension in such cases The results obtained showed that the blood-nitrogen figures are not raised as the result of the administration of vasodilator drugs for periods varying from 24 hours to over a week There is, however, in such circumstances usually an increased urea concentration in the urine after the exhibition of urea by the mouth A large fall in blood pressure following venesection in high pressure cases does not interfere with the excretion of urea —A Critical Analysis of Certain Laboratory Methods Applied to the Cerebro-spinal Fluid in the Serological Diagnosis of Neuro-syphilis, by H. Ferguson Watson An introductory account is given of the various laboratory tests applicable to the cerebro-spinal fluid in cases of neuro-syphilis, and of the results obtained by various workers The author investigated a large series of cases, both syphilitic and non-syphilitic In addition to a clinical examination the following tests were applied · the Wassermann reaction of the blood-serum and cerebro-spinal fluid, the colloidal gold test, the globulin tests, the cell count and the foam test Out of 100 cases clinically syphilitic the Wassermann reaction was positive in the serum in 96, and in the fluid in 97 The gold test was positive in 89 of these, and the globulin test in 95 In the non-syphilitic cases the Wassermann test was negative in serum and fluid in every instance, but the Lange test was positive in 45 out of 103 cases, which included such diseases as influenza, acute rheumatism, mumps, and chronic nephritis The author therefore concludes that the Lange test is quite unreliable in the diagnosis of neuro-syphilis —Observations on the Gastric Acidity and Secretion in Health, by T. A Butcher A series of personal experiments were made to determine the effect of pyschic stimulation on gastric secretion, the secretory response of the stomach to various articles of food, and the estimation of pepsin secretion It was found that difficulty in swallowing the tube causes a marked degree of hypo-acidity and gastric inertia Pyschic stimuli, on the other hand, such as chewing biscuits or sausages without swallowing, or the smell of bacon and tomatoes being fried, causes a marked increase in the acidity, total chlorides, and ferment curve Many interesting results were obtained on the effect of articles of food upon the gastric secretion, for details of which the article should be consulted Thus olive oil was not found to cause a lowering of acidity, nor was there an increased regurgitation of bile On the other hand, tea without milk was followed by results suggesting an inhibition of gastric secretion

INDIAN JOURNAL OF MEDICAL RESEARCH July, 1926 —Major A H Russell continues his exhaustive study of the epidemiology of cholera with illustrative tables D A Turkhud and C G Pandit *describe* an epidemic of an alastrim-like disease in Madras with some experimental investigations upon the virus Lieutenant-Colonel J Cunningham and T N S Raghavachari set out recent methods of differentiating lactose-fermenting organisms as applied to Indian conditions A valuable contribution to the study of heat stroke is supplied by Colonel F H G Hutchinson in Allahabad Brigade area In the progress report on researches in sprue (1924–25) N Hamilton Fairley, Lieut -Colonel F P Mackie, and their associates have done much to clear the ground for further original work on this intricate subject Major R B Lloyd and R G C Mitra contribute a timely paper on the Wassermann reaction in malaria Lieut -Colonel S R Christophers and Major J A Sinton provide a malaria map of India Asa C Chandler surveys the prevalence and epidemiology of hookworm and other infections in India and records the probable discovery of a new schistosome

New Inventions.

A DRESSING TABLE

THE dressing table here illustrated is useful as a part of the equipment of a consulting or small casualty room It consists in effect of a shallow rectangular box mounted in the form of a table The table top is formed out of two broad pieces of wood, or better of metal, hinged on a central narrow strip The interior of the box is divided up into compartments In the left side are placed instruments, ligatures, local anæsthetics, a kidney dish, pure carbolic acid, lysol, ether soap and spirit, &c In the right side are placed bandages, dressings, adhesive plaster, tr benzoin, iodine, &c The top of the left leaf of the table is provided with a mackintosh sheet, and a curtain which is capable of being swung across the table For example, a patient comes in with a cut hand He is seated at the left end of the table, instruments are chosen and sterilised, and the leaf replaced The patient places his hand on the table, and the curtain is swung across his view in order that he shall not see what is happening When the operation is concluded the right leaf is raised, tr benzoin co or tr iodine is dropped on the hand with a pipette (discarding the dirty method of using a brush for this purpose), and a dressing and bandage are applied The special advantages claimed for the table are (1) its convenience, all instruments, dressings, &c , being directly visible , (2) the contents are kept free of dust , (3) increased comfort of the patient, as he does not see his injury . and (4) small cost

ANANA BRIGHTENING SHAMPOO JELLY

(SEATON BURRIDGE, 4, WINDSOR PLACE, CARDIFF)

THIS preparation is used as a shampoo It is claimed to promote the growth of the hair, to give faded hair a gloss, and to remove any greasy appearance The jelly is green in colour and has an odour of verbena When analysed the following results were obtained —

Moisture	36 4	per cent
Mineral matter ·	10 3	,, ,,
Fatty acids	41 5	,, ,,

The soap is alkaline, due to the presence of potassium carbonate No free caustic alkali was detected Borax also was found The colouring matter is chlorophyll The jelly forms a good lather

SURVEY OF THE PUBLIC HEALTH

Sir George Newman's report to the Minister of Health[1] follows hard on that of his fellow Secretary, Sir Arthur Robinson,[2] and while the statesman may be regarded as keeping his finger on the pulse of the community in its reaction to the Public Health and Insurance Acts, the chief medical officer possesses an instrument more in the nature of an electrocardiograph on which are recorded the delicate responses of the body corporate to physical influences, and in which the difficulty lies not so much in record as in interpretation With that in mind the chief medical officer has been at pains to bring into being a section of the Ministry to deal with statistical intelligence a phrase which although of horrid aspect, lies deep in the foundation of effective public health administration It has been Sir George Newman s object to provide a section which, neither overburdened with pure routine however essential nor devoted to research work however interesting, should follow a middle path, educating itself and others in the use of medical statistics, and particularly in the use of official data of our own and other countries All through his report the chief medical officer shows a reluctance to associate effect and cause where a variety of interpretations are possible and a restraint in ascribing praise or blame to particular agencies or objects Nevertheless, there are passages in which he lets himself go in the one direction or in the other, as, for instance, in regard to the unrestricted spread of small-pox in several sanitary districts owing to neglect of well-known precautions An ill-administered district, he writes curtly, is a constant source of menace to its neighbours and to the country as a whole It acts as a reservoir from which an infection is liable to be carried to hitherto uninvaded areas And on the other hand, while admitting that data are as yet insufficient fully to assess the value of infant welfare centres, he gaily fills a page of the report with letters from tram conductors, printers clerks foster-mothers, and others who have appreciated these centres and have written to say so

At the end of the report Sir George Newman sets out the principal evidence concerning the physical life and health of the people of England and Wales during the year 1925, showing, in brief, a birth-rate of 18 3 per 1000—the lowest on record except for the war years of 1917–18 , a death-rate of 12 2 per 1000—the same as for 1924, with an incidence of 39 per cent of deaths on persons under the age of 50 years , an infant mortality rate of 75—the same as last year Notifications of infectious disease number round about 400,000, an immaterial change on last year The chief causes of death stand on the same numerical relation to each other as before, circulatory disease claiming 177 of each 1000 deaths, respiratory diseases 165, cancer 110, nervous diseases 99, and tuberculosis 85, and Sir George Newman's outlook does not allow him to state in so many words that these five diseases are the chief physical enemies of the country at the present time Disease, he states—and it is well worth while to reiterate it whenever possible in some new and striking form—is the reaction of the human body to irregularities of its whole environment, including various forms of infection The chief enemies are not the end-results but the earlier conditions which produce them and only the study of these will show directions in which effort is likely to succeed On tuberculosis the present line of attack is to reduce the chances of infection and strengthen the bodily resistance , cancer is to be held at bay by early detection which allows of removal or reduction of the new growth . any attempt to limit heart disease without differentiation of its causes is futile The mortality from respiratory disease leads to one of the chief medical officer s more dogmatic utterances Evidently, he writes, pneumonia is to a large extent a preventable disease, and the North of England has still much to learn with regard to its prevention

The medical staff which collates the materials on which Sir George Newman s survey is based consists of six sections each with its senior officer in charge Sir George Buchanan presides over the Section of General Health and Epidemiology, Dame Janet Campbell over that of Maternity and Child Welfare Dr F J H Coutts over that of Tuberculosis and Venereal Disease, Dr A. W J MacFadden over the Supervision of Food Supplies, Dr J Smith Whitaker over the General Practitioner Services. and Dr H A Macewen over Sanitary Administration in Relation to Infectious Disease Of the 15 full-time medical officers in Section I three direct the Pathological Laboratory Section II has four medical officers, all women, as well as women inspectors Section III has 7 full-time officers and commands the part-time services of Colonel L W Harrison Section IV includes 3 medical officers, a chemist, and 2 milk inspectors Section V has 4 full-time medical officers and a large regional staff distributed over the country Section VI in addition to its 9 medical officers has 2 officers attached to the Government Lymph Establishment The Welsh Board of Health constitutes a seventh section with Dr D Llewelyn Williams as senior medical officer. The field work of several sections is, of course, done by the medical officers of health with whose problems the report sympathetically deals, especially in relation to the division of responsibility in non-county areas between the supervision of environment and the oversight of personal hygiene , in Sections II and III by the clinical officers attached to the public health services , and in Section V by the practitioners whose names appear on the medical lists of insurance committees. These in their turn draw upon the ever-widening group of ancillary colleagues—dentists, midwives nurses, health visitors. sanitarians, engineers and the rest Coöperation on the part of this great community has produced the report presented by the chief medical officer of the Ministry, and that report is a practical testimony to the way the machine works and to the practical results

REACTION TO BLOOD TRANSFUSION.

For several years experiment and observation have been directed towards the elucidation of the cause of the so-called minor reactions which often follow transfusion of blood A variety of causes have been held responsible such as sodium citrate, the use of rubber tubes a fall in the temperature of the blood injected, and so forth. None of these has quite

SURVEY OF THE PUBLIC HEALTH

Sir George Newman's report to the Minister of Health[1] follows hard on that of his fellow Secretary, Sir Arthur Robinson,[2] and while the statesman may be regarded as keeping his finger on the pulse of the community in its reaction to the Public Health and Insurance Acts, the chief medical officer possesses an instrument more in the nature of an electrocardiograph on which are recorded the delicate responses of the body corporate to physical influences, and in which the difficulty lies not so much in record as in interpretation. With that in mind the chief medical officer has been at pains to bring into being a section of the Ministry to deal with statistical intelligence, a phrase which, although of horrid aspect, lies deep in the foundation of effective public health administration. It has been Sir George Newman's object to provide a section which, neither overburdened with pure routine however essential, nor devoted to research work however interesting, should follow a middle path, educating itself and others in the use of medical statistics, and particularly in the use of official data of our own and other countries. All through his report the chief medical officer shows a reluctance to associate effect and cause where a variety of interpretations are possible and a restraint in ascribing praise or blame to particular agencies or objects. Nevertheless, there are passages in which he lets himself go in the one direction or in the other, as, for instance, in regard to the unrestricted spread of small-pox in several sanitary districts owing to neglect of well-known precautions. An ill-administered district, he writes curtly, is a constant source of menace to its neighbours and to the country as a whole. It acts as a reservoir from which an infection is liable to be carried to hitherto uninvaded areas. And on the other hand, while admitting that data are as yet insufficient fully to assess the value of infant welfare centres, he gaily fills a page of the report with letters from tram conductors, printers' clerks, foster-mothers, and others who have appreciated these centres and have written to say so.

At the end of the report Sir George Newman sets out the principal evidence concerning the physical life and health of the people of England and Wales during the year 1925, showing, in brief, a birth rate of 18.3 per 1000—the lowest on record except for the war years of 1917–18; a death-rate of 12.2 per 1000—the same as for 1924, with an incidence of 39 per cent. of deaths on persons under the age of 50 years; an infant mortality rate of 75—the same as last year. Notifications of infectious disease number round about 400,000, an immaterial change on last year. The chief causes of death stand on the same numerical relation to each other as before, circulatory disease claiming 177 of each 1000 deaths, respiratory diseases 165, cancer 110, nervous diseases 99, and tuberculosis 83, and Sir George Newman's outlook does not allow him to state in so many words that these five diseases are the chief physical enemies of the country at the present time. Disease, he states—and it is well worth while to reiterate it whenever possible in some new and striking form—is the reaction of the human body to irregularities of its whole environment, including various forms of infection. The chief enemies are not the end-results but the earlier conditions which produce them, and only the study of these will show directions in which effort is likely to succeed. On tuberculosis the present line of attack is to reduce the chances of infection and strengthen the bodily resistance; cancer is to be held at bay by early detection which allows of removal or reduction of the new growth; any attempt to limit heart disease without differentiation of its causes is futile. The mortality from respiratory disease leads to one of the chief medical officer's more dogmatic utterances. Evidently, he writes, pneumonia is to a large extent a preventable disease, and the North of England has still much to learn with regard to its prevention.

The medical staff which collates the materials on which Sir George Newman's survey is based consists of six sections, each with its senior officer in charge. Sir George Buchanan presides over the Section of General Health and Epidemiology, Dame Janet Campbell over that of Maternity and Child Welfare, Dr. F. J. H. Coutts over that of Tuberculosis and Venereal Disease, Dr. A. W. J. MacFadden over the Supervision of Food Supplies, Dr. J. Smith Whitaker over the General Practitioner Services, and Dr. H. A. Macewen over Sanitary Administration in Relation to Infectious Disease. Of the 15 full-time medical officers in Section I three direct the Pathological Laboratory. Section II has four medical officers, all women, as well as women inspectors. Section III has 7 full-time officers and commands the part-time services of Colonel L. W. Harrison. Section IV includes 3 medical officers, a chemist, and 2 milk inspectors. Section V has 4 full-time medical officers and a large regional staff distributed over the country. Section VI in addition to its 9 medical officers has 2 officers attached to the Government Lymph Establishment. The Welsh Board of Health constitutes a seventh section with Dr. D. Llewellyn Williams as senior medical officer. The field work of several sections is, of course, done by the medical officers of health with whose problems the report sympathetically deals, especially in relation to the division of responsibility in non-county areas between the supervision of environment and the oversight of personal hygiene; in Sections II and III by the clinical officers attached to the public health services; and in Section V by the practitioners whose names appear on the medical lists of insurance committees. These in their turn draw upon the ever-widening group of ancillary colleagues—dentists, midwives, nurses, health visitors, sanitarians, engineers and the rest. Coöperation on the part of this great community has produced the report presented by the chief medical officer of the Ministry, and that report is a practical testimony to the way the machine works and to the practical results.

◆

REACTION TO BLOOD TRANSFUSION.

For several years experiment and observation have been directed towards the elucidation of the cause of the so-called minor reactions which often follow transfusion of blood. A variety of causes have been held responsible, such as sodium citrate, the use of rubber tubes, a fall in the temperature of the blood injected, and so forth. None of these has quite carried conviction with those who practise transfusion, and it is of interest to note that some new observations published this year seem to come nearer the mark than any that have gone before The first of these is an article[1] by Dr **Charles A Doan** on the Recognition of a Biologic Differentiation in the White Blood Cells This author observes very justly that there are too many factors entering into every transfusion for it to be possible to give to any one of them the full responsibility for the reactions He claims, however, to have demonstrated that, in addition to the well-known incompatibilities between the serum and red cells of different individuals, there is a similar and definite incompatibility between the serums and the white cells A biologic classification according to groups has not yet been achieved as there seems to be a large number of possible combinations, but it was estimated that about 40 per cent of the individuals investigated were ' universal donors " as regards their white cells, these were, of course, not necessarily the same individuals as belong to the red cell group IV of Moss Dr **Doan** suggests that before transfusion the white cells of donor and recipient should be directly matched as well as the red cells He believes that the destruction of white cells goes on gradually as the blood is transfused until enough foreign protein has been liberated in the patient's circulation to produce a reaction This might explain the fact that the reaction usually occurs about half an hour after the transfusion is completed A contribution of a different kind comes from Dr **Roby Jones** and Prof E E **Glynn**, of Liverpool University.[2] These authors have made an elaborate investigation of the red cell blood groups of 40 healthy individuals by cross-agglutination and by absorption tests, each agglutination being done in five dilutions The tests were very delicate and revealed seven abnormal donors among the 40 investigated All these seven agglutinated with another member of their own group, and three of them belonged to group IV The authors suggest that these results may indicate the existence of abnormal blood groups, and may explain some of the unexpected clinical symptoms after transfusion Another step forward is recorded by Dr F W **Simson**, of Sheffield University[3] He has directed his attention to the isolation of a third pair of agglutinating factors in human blood in addition to the two pairs constituting the four groups of Moss and Jansky Other observers have already claimed to have demonstrated this Dr **Simson** now confirms their observations and finds that the presence of the third system can be readily demonstrated by absorbing a group III serum of a particular type with a group II serum, and testing with the resulting serum He finds that the third system is present in a large percentage of human bloods, but is not detected by the ordinary methods of testing He finds further that the system designated in the Jansky-Moss classification by the letter A is occasionally suppressed The blood of an individual in whom the A system is absent will appear to belong to group IV (Moss), although his blood is actually incompatible with other members of group IV Fortunately such individuals are rare, but the discovery goes to prove that the term " universal donor " for members of group IV is a misnomer, as some authorities have always maintained Whether we have to deal with abnormal groups, or rather, as now seems likely, with additional normal groups, it becomes more desirable than ever that a cross agglutination test between donor and recipient should be done wherever possible, and that every transfusion should be conducted very slowly at the beginning so that an unexpected reaction can be detected before serious harm has been done

INTERNATIONALISM IN PORT SANITARY WORK

The Fourth International Sanitary Conference has been recently held at Paris, when 70 nations were represented, including, as separate signatories, the dominions of Canada, Australia, and South Africa and British India The Conference had the duty of bringing up to date and revising the International Sanitary Convention under which the various signatory Governments in 1912 agreed on mutual action and common standards for dealing with the chief diseases liable to be carried by shipping, among which the pestilences of cholera and plague have far the greatest significance The Conference was a success, and has laid down new lines of international action of the first interest for those concerned in the health regulations of our ports, a matter which affects not only the whole of this country but, by reflection, all other shipping centres and the nations on whose lines of world communication these centres are The apparently complicated organisation through which mutual action is now set up between civilised Governments for the prevention of epidemic invasion is, it would seem, working thoroughly well The delegates at the International Conference influence and revise the procedures upon which the various Governments act at the instance of the International Convention, while the information forthcoming at the half-yearly meetings of the Office Internationale d Hygiène Publique, sitting permanently in Paris, is on the one hand available for the Convention, and on the other for the League of Nations, for the Office Internationale now acts as an advisory council to the health organisation of the League, which is therefore in a position to assist all port sanitary work The enormous potentialities of the League of Nations in regard to the maintenance of the health of the world should be ever present to our minds, patriotic jealousies may be inherent in the development of the League, but a really international affair like the health of the world must not be impeded by racial sparring And recollection of this is timely while the League is in session

Before the Royal Sanitary Institute at the recent jubilee meeting Sir **George Buchanan** opened a discussion upon the present position of international agreements as they affect port sanitary work and the International Sanitary Convention, and throughout the address he considered the position of plague, its incidence and carriage, in illustration of the progressive work now undertaken by the representative sanitary authorities of the world The great plague epidemic, which began in China over 30 years ago and extended almost immediately to Bombay, thereafter to gain a permanent footing in India, *imposed* on port authorities a revision of their administrative machinery and a search for all the scientific resources which they could command Thus, in face of a new set of problems, epidemiologists and bacteriologists have supplied an increasing range of pertinent knowledge The result has been that we now know that plague infection, when carried by ships, cannot be dealt with in the same way as the infection of cholera, and further, that not only will international codes require variation in respect of different diseases, but that a particular disease, plague for example, cannot be fought with identical methods at all centres The old and cruel preventive system, recalled in the word "quarantaine," has long been superseded, owing, we may be proud to think, to the resolute opposition of British sanitarians, but the humane and scientific methods which succeeded have required regular modification with the growth of knowledge It is not enough to examine passengers and crews from infected areas, or to provide isolation and surveillance for sick people and contacts, nor is it permissible to await the occurrence of human plague on a ship before taking measures for the destruction of rats, as rats became recognised as the essential villains of the story, preventive precautions had to be altered in direction "Port sanitary authorities all over the world, though for different reasons and in different circumstances' said Sir GEORGE BUCHANAN, 'have direct interest in the suppression of rat plague on ships, in preventing the access of rats from ship to shore, and in keeping down the rat population in wharves, docks, and warehouses" This much is common knowledge, and we may assume all those interested to have read the useful publications of the Ministry of Health on the subject Those who on account of their particular avocation are compelled to study port sanitation are familiar with the different methods employed in fighting rats on ship or shore, and on their intermediate passage But it may easily happen that early steps have to be taken by those whose immediate work is not of a sanitary nature Both in South Africa and Australia this is recognised, and quite recently in Australia the Commonwealth Department of Public Health has brought out a handbook for the guidance of customs officers which contains an outline scheme for dealing with an outbreak of plague in a port in a practical manner The rat is a doughty foe, and it is largely on account of his irrepressibility that the Australian handbook considers it necessary to go into minute details of staff, office accommodation, and even the number of telephones that may be needed to repress a sudden invasion of plague The public may guess how much the world's immunity from pestilence is due to the great organisations outlined above, but Conferences and Conventions would be futile without the devoted attention of individual port officers, and this is a thing which deserves grateful attention

[2] A Roby Jones and Ernest E Glynn Jour of Path and Bact, 1926 xxix., 203

[3] F W Simson Ibid, July, 1926, xxix., 279

While recent developments against the attacks of plague, including various methods of rat destruction, are valuable, they none the less bring with them certain difficulties which have to be considered from an international aspect, and the arguments for thinking internationally in regard to plague, and even in regard to one side of the prevention of plague could—mutatis mutandis—be applied to the whole range of epidemiology If every country in the world applied the full force of its quarantine or port sanitary service, and all its experience, to prevent every possibility of the inter-carriage of infections, regardless of what was being done or had been done in this respect by any other country there would be such an overlapping of inspections that the business of the world would be seriously hindered These are the difficulties which the International Sanitary Convention exists to take into account, adjust, and minimise, and the regular revision of the Convention's regulations should keep pace with the world's progressive accumulation of scientific wisdom The dissemination of news by wire and air will have beneficial results exactly as the machinery exists for prompt action upon information

Annotations.

"Ne quid nimis"

HOSPITALISATION OF THE ASYLUM SYSTEM

WHEN the future historian surveys the treatment of mental disorder he will probably divide its development into three age-periods The first will be that in which the mentally afflicted person was regarded as a criminal and the second that in which he was regarded as a wild animal The first quarter of the twentieth century has marked the transition from the second to the third stage, in which he is being regarded more and more as a sick man In the era just passed the patient of mental disorder was not far from being in the position of a wild animal housed in a humane zoological gardens, his physical necessities were provided, with such additional comforts as charity or private means could procure, and he was firmly enclosed in a safe cage lest he molest the remainder of mankind If by a happy chance he struggled back to a standard of conduct compatible with civilised life, he was released from his cage and a veil of scandalised silence was drawn over his past, as far as possible, that is, for society never dreamed of admitting a comparison between a disordered brain and a disordered stomach, or of looking on an attack of mania in the same light as an attack of diarrhœa and vomiting

The progress made in right thinking on these matters in the last 20 years has been remarkable, and it is of the highest importance that the success already achieved should be followed up It may be that the stress of war and the steadily increasing strain of modern life has quickened our sympathy and our intuitive understanding of the mental state of those who have just failed to keep pace with the stream Now that the majority of people only maintain their headway with difficulty, they are able to realise that the "insane" patient is not of a different genus, a thing strange and abhorred, but of like nature with themselves, reacting as they would react if the screw were turned a little tighter The great obstacle in the way of those who have the peculiar training and ability to translate this understanding into active help is that, once beyond a certain point, the lines of communication are broken, and in the present state of our knowledge it seems impossible to get any message through to the beleagured garrison of a psychotic mind The physician can only stand outside, ever on the watch, and give what relief he can by setting disordered bodily processes at rest But before this stage is reached there is invariably a prodromal period when much can be done, and the most tragic reminder of the "wild animal" era that we have still to face is the fact that this critical time is one when the help and the need are usually separated by a gulf of tradition and false thinking Relatives and patients alike refuse either to acknowledge or to take seriously the first symptoms of mental disharmony It is also unfortunately true that the average practitioner is still untrained in the treatment of such cases and that both he and the public shrink from the mental specialist and send for him only when the time for helping is past Much responsibility, in this as in all departments of public health, lies on the general practitioner, and if the harvest of the psychiatric revolution is to be garnered successfully some means must be found of bridging the educational gap between the neurological out-patient department and the hurried course in the wards of a mental hospital

The annual report of the Board of Control[1] shows this year again how strenuous are the efforts of the statutory authority to ensure the adequate advance of psychiatry. One of the measures to this end is the provision of centres for out-patient treatment The Commissioners remark that they are "satisfied that such centres are productive of very great good, and that, in the public interest, it is important that they should be extended " Unfortunately, it is still only in a comparatively few areas that the work, first commenced in the West Riding of Yorkshire, is being extended Its value is inestimable, and, unfortunately, it is much restricted in many places by the fact that no special beds are available and that the institutions are not yet allowed to admit their out-patients as voluntary boarders It is most discouraging to read that certain local authorities still refuse to admit uncertified patients because of the loss of the small grant which they receive for those legally classed as " lunatics " Such a grant interpreted in such a way puts a premium on incurable mental disorder The social conscience of the public should not be satisfied until every mental hospital receives voluntary patients; only in this way will the number of certifiable cases be reduced and the percentage of cures raised Although " asylum fear " is greatly reduced by attendance at such out-patient departments, the Commissioners recognise its deterrent effects and encourage mutual arrangements wherever possible between general and mental hospitals In this way the resident staff of the latter can attend the general hospital as out-patient physicians In every revolution some valuable feature of the old system is overthrown, and it is permissible to regret the arrangements of the eighteenth and early nineteenth centuries whereby rooms were set aside in most general hospitals for insane patients To make room for the steadily increasing number of people who are willing to enter a mental institution before their trouble is incurable, some way must be found of extending the accommodation, which is seriously overcrowded in most parts of the country The modern mental hospital is a highly equipped institution, and is too elaborate an instrument to be used for harmless senile patients, for whom nothing curative can be done and who need only that the way to death should be made smooth and peaceful An approach has already been made to certain boards of guardians with a view to housing these old people in the Poor-law institutions, and the Board of Control desires that such arrangements should become general The great problem raised by the measure is the education of infirmary nurses in the proper care of these none too easy patients

---

[1] The Twelfth Annual Report of the Board of Control for the Year 1925 H M Stationery Office 1926 Pp 468 12s 6d

There are many other respects in which the up-to-date mental hospital is rapidly becoming a microcosm of modern treatment No such institution is complete without a visiting dental surgeon, and the Commissioners urge the appointment of a consultant in each of the specialties Whatever the cause of mental disease may be, hidden septic foci, disordered metabolic processes, and faults of the special senses can but prolong the struggle for equilibrium, 30 per cent of the mental hospitals are without a properly equipped pathological laboratory and trained pathologist, and the Board believe that these are essential from the point of view both of patients and staff They also feel strongly the need for an X ray installation and a radiologist, noting certain instances in which the elucidation of symptoms has been either impossible or detrimentally delayed by the absence of X ray facilities Clinical rooms for simple investigations, note-taking, and informal and therapeutic conversations are necessary for the proper conduct of cases and are being provided in most of the hospitals One of the most striking and valuable features in the hospitalisation of the asylum is the granting of parole and " trial trips " before discharge The mental condition of responsible people who are in psychological conflict is undoubtedly made worse by locked doors, censored correspondence, and all the relics of the prison system No harm has resulted from the judicious use of open-door wards and verandahs, freedom of action within the grounds, and provisions of tobacco and small comforts Many a superintendent has blessed the new system which enables him to send a recovered patient out with sufficient money to tide him over the first difficult weeks of readjustment, when the added problem of financial stress would almost certainly mean another breakdown

BENZOL POISONING AS AN INDUSTRIAL HAZARD

COMMERCIAL benzol is a coal-tar distillation product of which the chief constituent is benzene, C_6H_6 It is coming more and more into industrial use as a solvent for rubber, gums, fats, and resins, as a starting-point in the manufacture of coal-tar products and chemicals, and as a motor fuel blended with petrol. Its toxic properties were first recognised after a coroner's inquest in 1862,[1] and steps have since been taken to control the risk which exists in its manufacture and use A committee in America has been studying the position since 1922, and now three articles summarising their work have appeared [2] In the manufacture of benzol, the blending of motor spirit, and the chemical industries, the hazard is so great that stringent precautions are taken and mishaps only occur due to their breakdown, but when benzol is used as a solvent, at any rate in the States, in the rubber industry, artificial leather-making, sanitary can manufacture, dry cleaning, or in manipulating paints and varnishes, danger from inhaling benzol vapour is considerable A résumé is given of all known acute cases which have usually occurred through accidental exposure to vapour in closed spaces, such as coal-tar stills, benzol holders, or when painting the inside of tanks The vapour of benzol is heavier than, and so displaces, air A worker feels headache and dizziness and may then sink into the trough of vapour to be asphyxiated Only rapid removal into fresh air can save life, but many unprotected rescuers have failed in their efforts and have themselves been overcome Acute cases are either rapidly fatal or respond quickly to treatment, but there may be after-effects Air containing 0 5 per cent will produce confusion within half an hour, and from 0 6 to 0 9 per cent poisoning within a few hours Acute cases are, however, rare compared with chronic cases due to inhaling low concentrations over prolonged periods which have occurred in applying rubber dissolved in benzol to tin cans, in spreading rubber cement, and in rubber-tyre building Details of several cases are given Young girls exhibit a marked susceptibility Serious results ensue from prolonged exposure to air containing 0 2 per cent of benzol vapour The usual symptoms are headache, dizziness, palpitation, bleeding gums, frequent menstruation, and blue spots on the arms and legs, with secondary anæmia, the leucocyte lymphocyte formula being inverted Nervous symptoms indicating sclerosis of the dorsal columns and pyramidal tracts follow Leucopenia may be severe, and the red cell count be below 500,000, with hæmoglobin as low as 15 per cent Animal experiments, for the most part confirmatory of observations on human beings, carried out by many workers, are summarised, they bring out that resistance to microbic infections is diminished by benzol poisoning An effort, confessedly incomplete, was made to ascertain the extent of the benzol hazard in the United States through a questionnaire sent to firms likely to be concerned By this means 15 fatalities and 83 cases of sickness were traced previous to 1925, 29 compensable cases in the State of Ohio in five years, and seven fatalities during the first nine months of 1925 Next the committee undertook an intensive study under factory conditions of atmospheric pollution by benzol The method of testing employed was to absorb any benzol vapour present in activated charcoal, and a description is given of the apparatus used Concentrations of solvent vapours were detected varying from 40 parts to 4140 parts per million of air The blood of 81 persons employed in the atmospheres sampled was examined, and in 26 cases the findings were positive for benzol absorption, the standard chosen was a white cell count of less than 5500 per c mm Histories are given in detail of two cases which justified the diagnosis of aplastic anæmia Undoubtedly as benzol is used to-day it involves a substantial industrial hazard Even when the concentration is below 100 parts per million all risk is not avoided owing to the great personal idiosyncrasy of some individuals The use of substitute solvents of less toxicity is the only sure remedy Meanwhile exposure to risk should be minimised by preventing benzol vapour from escaping into work places or by withdrawing it at its point of origin And steps should be taken to detect incipient cases of poisoning and withdraw them from risk, standards of initial health before employment, and of symptoms calling for suspension, are proposed The full study made by the committee is to be published later, but the present preliminary articles exhibit benzol as an insidious industrial hazard The bibliography attached to the third article indicates how widespread is this hazard

THE TREATMENT OF PSORIASIS

IT is the experience of most British dermatologists that the treatment of psoriasis by injections is, as a rule, ineffective unless supplemented by vigorous local measures This opinion was emphasised by Dr R McKenna in his opening address to the discussion on the treatment of psoriasis, which we report on p 550 Neither he nor those who followed him appear to have made a trial of tartro-bismuthic salts which Dr A. Versari,[1] of Naples, claims to have used with some degree of success Sabouraud's conception that the modern treatment of psoriasis should be directed to the discovery of some substance that, under the form of injections, is capable of influencing the lesions without recourse to local applications, has lately been applied by Dr Versari It has long been believed that psoriasis is sometimes favourably influenced by injections of grey oil, enesol, and arsenobenzol even in the absence of signs of syphilis, and that salts of bismuth have a definite spirochæticide action, as shown by Levaditi and Castellani in the spirochætosis of rabbits and fowls Prowazec and Rasck, of Christiania, claim to have isolated a similar organism which they name *Spirochæta sporogona psoriasis* These researches influenced Dr Versari in experimenting with an organic preparation commercially known as *Trepol*, which is an oily suspension of tartro-bismuthate of soda and potash containing 60 per cent of bismuth Intramuscular injections every five to six days in doses of 2–3 c cm were given in 21 cases, they were well tolerated, no stomatitis or renal trouble occurring, and the gingival rim formed very slowly and never reached the intensity noticed in syphilitics treated with bismuth Out of the 21 cases under observation, no local treatment being given, a complete retrogression of the lesions took place in 12, in the other nine there was partial regression, desquamation, and diminution of the hyperæmia All the patients had relapses but always in a much smaller degree, except one who had no relapse from November, 1924, till January, 1926, not having been given any injections since June, 1925 In three patients a psoriasic leucoderma appeared after the cessation of the lesions Histological examination of these patches showed (1) depigmentation of the epidermis from disappearance of the epithelial chromatophores and marked scarcity of the connecting filaments, (2) persistence of the granular layer, (3) slight increase in the superficial layers without parakeratosis; and (4) hypertrophy of the collagen fibres in the deep portion of the reticular part of the corium Researches made on smears from the lesions failed to discover the *Spirochæta sporogona psoriasis*, but linear or spirilliform bodies were seen coloured violet-red by Giemsa, sometimes isolated but more often in masses They were regarded as probably connective tissue fibres or macerated elastic tissue In the absence of any positive evidence of the presence of an organism the action of the bismuth injections cannot be explained as spirochæticidal, and investigations directed to detect the presence of bismuth in the retrograde patches of psoriasis were without result Dr Versari is inclined to agree with Sabouraud's opinion that the various injections which have been used with success in the treatment of psoriasis, such as calomel, enesol, cacodylate of soda, camphorated oil, antitetanic and antidiphtheritic serum, simple horse serum, Danysz's entero-vaccine, including preparations of bismuth, may be considered as working by shock production Most of his colleagues in this country will agree with this view, but it does not follow that certain of these preparations are not more effective than others in producing shock of the right kind or degree

THE TWO GIBRALTAR SKULLS

THE Abbé Breuil, some years ago, noticed and called attention to Mousterian remains in the neighbourhood of the Devil's Tower at Gibraltar, and a result of his observations was seen at the recent meeting of the British Association at Oxford, when Miss D A E Garrod described the fruits of her excavations in this place Among other things, a young human cranium was found, embedded in hard travertine, under conditions which make it practically certain that its original owner belonged to the period represented by its immediate surroundings and accompaniments Mr L H Dudley Buxton seems to have been very successful in freeing the specimen from its matrix, and has already advanced tentative reconstructions and suggestions based on his work it is, of course, too early to do more in this place than record the discovery, as the remains will have to undergo a lengthy and exhaustive examination before definite announcements can be made about the cranium, which is that of a child This skull, referred to in the lay press as the "Gibraltar skull," is not really entitled to this name as a distinctive label, for many years ago another discovery was made close to the site of the present one This original find, the "Gibraltar skull" of anthropologists up to the present, was found in 1816 in the Forbes Quarry Its present-day value was not assigned to it for many years, however, and the uncertainty about its date is still a stumbling-block in the way of definite recognition by many, although it is now generally admitted to be of great age It has been considered a female relic While Gibraltar I is thus still doubtful in some ways, and hence stands somewhat in the background at present, the cranium now brought forward, Gibraltar II, is undoubtedly authentic as a Mousterian relic, presumably from one of the Neanderthal race *Homo neanderthalensis* was a human being of a low order, whose known anatomical remains are now sufficient in number to allow of more or less clear ideas of his characteristics, and distribution, to be formed His kind inhabited the old world, at least through several epochs, and apparently died out after the end of the glacial period Although no doubt a very unpleasant fellow according to modern standards, he was not a wild beast, but possessed a large brain and had a culture of his own; this improved as the ages went on, and it is customary to recognise different types of it, Chellean, Acheulian, and Mousterian, these names being given with reference to certain places where typical and undoubted examples have been demonstrated. The Mousterian is the last of these types, and covers the last glacial period Neanderthal man overlapped higher cultures and human types, but whether he mixed with these and bred with them, or whether he lived and died apart as a separate species or a lower race, is not apparent He is not generally looked on as in the direct line of ascent of modern man, but he is none the less a most fascinating study and problem, and everything which makes for further acquaintance with his form or his family, or his haunts and history, is of great interest. Gibraltar II is not the only specimen of a young form that has been obtained, for remains of children were found at Ferrassie and at La Quina, while the skull of a youth at about the age of puberty was among the discoveries at Le Moustier this last was remarkable in the great development already of the heavy skull and brow-ridges which are characteristic of the race When the latest addition is ready for complete examination it will without doubt provide many features of interest, both with reference to questions affecting its geological contemporaries and for purposes of comparison with other and more modern young skulls Sir Arthur Keith describes it as the first representative Mousterian skull of a male child, and puts its age as between 20,000 and 40,000 years

FEAR REACTIONS IN THE CHILD

An episode that recurs in almost stereotyped form was described last week at an inquest upon a child who fell into the *Mersey* whilst at play with three others, who were too frightened to tell anyone Accidents are inevitable as long as rivers and children are in proximity, but such behaviour as the companions of the victim showed is not inevitable, yet it occurs with sufficient frequency to make us suspect that the cause is to be found in general principles rather than in individual tendencies In our last issue we commented upon a parallel case in which a coroner severely condemned a lad of 15 who had hidden the fact of a playmate having been shot in the palm The Warrington coroner adopted a different attitude in trying to lessen the remorse shown by the boys concerned in the drowning accident, and when we consider the impression that a fatal disaster can make upon adult participants we must agree that in such cases no words are wasted that can alleviate self-reproach in a child We might, nevertheless, differ from the coroner's view that the three were silent because "you can't put old heads on young shoulders" and "boys of their age have not been trained to think and do what was the right moral thing to do" They knew as well as any adult what was the right thing to do, but were prevented from doing it by fear, and it is fear that leads to such incidents Apart from knowledge, the instinct of the child is surely to turn to the adult for help; the secretive behaviour we are discussing indicates an inhibition rather than a lack of knowledge or moral training, and its causes are to be sought in our attitude towards the child Perhaps we may reach an understanding of the mind of the child in such circumstances when we remember what care we take to avoid any censure upon sufferers from venereal disease lest that may lead them to hide it If such care is necessary between man and man, we must recognise the need for avoiding the introduction of fear into the relation between the child and the omnipotent grown-up Besides its influence upon behaviour, this fear is shown by modern research to underlie many nervous symptoms both in children and those of mature years—playing, indeed, a part greater than that played by actual terrifying incidents

SANATORIUM TREATMENT OF TUBERCULOSIS

The efficacy of sanatoria in the treatment of tuberculosis has been questioned a good deal in recent times, and a number of attempts have been made to measure the results which they have obtained and are obtaining The question is very complicated and it is difficult to get a certain answer The latest contribution, by Dr Percy Stocks and Mr M N Karn, is published from Prof. Karl Pearson's laboratory in his *Annals of Eugenics* (vol i, 1926, p 407), and their inquiry appears to have been made with unusual care and thoroughness They deal with the histories, over a period of six years, of 2794 consecutive cases of undoubted pulmonary tuberculosis brought under the survey of the Belfast tuberculosis dispensaries from 1914 onwards Of these rather more than one quarter went to sanatoria, while the rest received only dispensary or domiciliary treatment These two groups are compared with one another as regards death, general progress and condition after six years and each is divided into three categories of severity of disease when first seen as judged by a combination of anatomical and symptomatic data For a discussion of the various pitfalls and uncertainties with which such an investigation is surrounded the original memoir must be consulted But the authors reach without hesitation the summary conclusion that the ultimate progress of patients first seen in the incipient stage was worse in those who went to sanatoria than in those who did not, in those in the "moderately advanced" and 'far advanced' categories the progress of the two groups was the same These conclusions hold good for both sexes, and for young people as well as adults The obvious criticism is that some sort of selection was exercised in choosing cases for sanatorium treatment which was related in some way to prognosis The authors devote much attention to this point and, after examining all the circumstances which they can think might have any such influence, they conclude that if selection was made on any significant basis they cannot discover what it is Many people will be loth to be persuaded off-hand that sanatorium treatment does phthisical patients no good, and it is in no depreciatory spirit of the careful work of Dr Stocks and Mr Karn that we suggest that it would be well if other statistics were similarly and independently examined in the light of their methods and commentary, including their suggestion that it is the depressing mental atmosphere of sanatoria which does the harm It may be that there is some particular type of person who does badly under sanatorium conditions, the identification and exclusion of these might perhaps change the mass statistics to the more favourable complexion which most people believe, perhaps groundlessly, that they ought to have Meanwhile it is well to remember that sanatoria exist for at least three purposes to ameliorate the physical state of the individual patient, to teach him how to manage his life successfully after he leaves the institution and to spread this information by his example, and to protect others from infection The present criticism deals only with the first of these objects.

THE MENACE OF OBESITY

We alluded last week (p 508) to the diminished expectation of life for those in whom the circumference of the abdomen exceeds that of the chest Investigations carried out on a large scale in America have shown that the optimum weight for a man of 45 years is about 20 lb less than the accepted average weight for that age, using the term "optimum" in relationship to physical fitness from the standpoint of an insurance company The steady decline in physical efficiency which the carrying of 20 lb of superfluous matter entails should in itself be sufficient antidote to the dangerous self-complaisance with which the middle-aged man views an increase in his girth If this is not enough, a perusal of Dr Leonard Williams's new book on Obesity[1] will quickly frighten him into a more satisfactory frame of mind The infiltration of fat into the subcutaneous tissues may result in a raised blood pressure from increased peripheral resistance, and against this high blood pressure a heart embarrassed both on its surface and throughout its musculature has to work under diminished efficiency Renal disease is extremely likely to follow such a condition of affairs, and it is not surprising to learn that the mortality from cardiac and renal diseases among the obese is twice as high as in persons of normal weight To make matters worse, it is notorious that such a diseased heart may give rise to very little in the way of symptoms and nothing in the way of local physical signs, and yet as Dr Williams emphasises, the fat man may die the next time he hurries to catch a train *Obesity* does not stop at producing disturbances of the circulatory apparatus The respiratory system may suffer and it is well known that certain asthmatics may be greatly relieved by cutting down their weight. Various troublesome forms of dyspepsia may result from over-weight, while invasion of the liver increases such troubles and the pancreas itself may suffer, leading probably to the form of diabetes associated with obesity. Intertrigo, varicose veins, hernia, and even deafness are some of the minor disturbances for which obesity may be blamed, to say nothing of the increased gravity of the prognosis of acute diseases in the obese subject. The cure of obesity is largely bound up with the problem of its causation. Perhaps the most striking advance on the subject within recent times has been the proved complicity of the endocrines leading to the broad classification of obesity into that caused by alimentary surfeit and that caused by underaction of one or more endocrine glands. The famous Daniel Lambert, who died at the age of 40 weighing nearly 53 stone, may safely be put into the latter category; but it is admitted that most of the obesity commonly seen about middle age is due to over-feeding. "To the scientist," wrote Vance Thompson, "there is nothing so tragic on earth as the sight of a fat man eating a potato." This quotation from Dr Williams's book may give perhaps the keynote to the solution of the problem. It is not generally realised that it is the starchy carbohydrate foods rather than the more quickly and readily metabolised fats which are responsible for much of the alimentary type of obesity. More rational diet will go a long way to preventing this troublesome complaint, and in its cure this notion must be firmly established in the mind of the patient. The arguments for and against muscular exercise (which may actually lead to an increase in weight, especially in endocrine cases), rest in bed, fasting, the use of thyroid extract and special diets, such as that associated with the name of William Banting, the undertaker of St James's-street, are still very complex. The influence of climate, race, and heredity comes into their discussion. What is certain, however, is that obesity is a serious menace to health and, far from being an enviable state, it is one which requires close attention.

THE AFTERMATH OF WAR.

THERE is no unofficial organisation for relieving the physical wreckage of the late war and helping the more or less disabled to help themselves which does more valuable and less ostentatious work than the Joint Council of the Order of St John of Jerusalem in England and the British Red Cross Society, which has just issued its sixth annual report. That it appears only five months after the end of the Council's financial year is an indication of the business-like fashion in which its affairs are managed. It has been a year of internal change, Dr F N Kay Menzies, who succeeded the late Sir Napier Burnett as Director of the important Hospital and Medical Services Department, having been appointed principal medical officer to the London County Council, and Mr R H P Orde, who has had a long experience of the Department, having taken his place as Acting Director. The Council has always been well served, and there is every reason to hope that the loss of two distinguished directors in rather rapid succession will in no way reduce the value of its work. That work is not confined to dealing with the disabled, for it keeps as watchful an eye upon the provincial hospitals as the King's Fund does upon those in the London district, and manages an ambulance service which annually breaks its own "records," and thus helps very materially towards filling a gap which is even now by no means completely closed. The purely after-war activities of the Council, as set forth in the report, are many and extend to all ranks of the Services, but perhaps the most important of them are those undertaken by the Auxiliary Hospitals for Officers Department which seeks to relieve ex-officers suffering from sickness or disablement attributable to, or aggravated by, their service in the war. More than 17,500 of such cases have been helped during the last six years, and it is melancholy to have a record that the majority of them have been tuberculosis cases. The Department puts them into hospital at Brighton, assists them to go to Switzerland or the Riviera, helps them with the cost of treatment while their cases are being officially investigated, and does not pass over unnoticed those whose applications have been rejected by the Appeal Tribunal. There are, unhappily, still many ex-officers who require surgical, medical, or convalescent treatment for disabilities for which the Ministry of Pensions could not accept liability, but are unable to pay operation and nursing home fees. Here the hospital steps in with its inestimable boons and removes much bodily suffering and mental anxiety. As regards mere extent, however, the activities of the Emergency Help Committee stand at the head of all these works of mercy. Last year 17,535 cases were helped, and £100 000 a year is being spent, mainly in grants of a fixed amount, for some specific purpose calculated to confer permanent benefit. Very often the money is eventually refunded, and many men, their physical handicaps notwithstanding, have thus been enabled to become self-supporting. In addition to all this money is found for materials and training for bedside occupations, for drives and entertainments and for Christmas gifts. The report makes a splendid record of public service, most of it performed voluntarily by helpers whose patience and sympathy provide the human touch that lights up so many lives upon which the shadow of war has fallen, never entirely to be removed.

ACUTE NEPHRITIS IN CHILDREN

A STUDY of the characteristics of the two principal forms of acute nephritis met with in children by Dr Kenneth D Blackfan,[1] of the Harvard Medical School, contains many points of interest. Dr. Blackfan's account suggests that the differentiation of these types is more complete than is usual in this country; of 41 cases 24 were definitely glomerular and 14 tubular, only three being mixed types. None of the cases described were scarlatinal. A table shows the distinctive features of the two types. Among the characteristic signs of glomerulo-nephritis are marked hæmaturia, high non-protein N-content of the blood, increased arterial tension, and frequent occurrence of uræmia. The tubular form is characterised by marked albuminuria and œdema, normal arterial tension and non-protein N-content of the blood, and the rare occurrence of uræmia. In fatal cases the condition of the brain showed distinctive differences which are held to be of significance in determining the presence or absence of the so-called uræmic symptoms. The author prefers to call the latter "cerebral" symptoms, as he believes that they are the results of mechanical intracranial conditions rather than of raised blood-urea. In tubular cases the brain showed a spongy œdema, comparable to that of the tissues, while in glomerular cases it was firm and tense, with flattening of convolutions and a tendency to the formation of a medullary pressure-cone. It is suggested that the causal sequence of events is (1) œdema of brain, (2) increased intracranial pressure, (3) raised arterial tension and the symptoms commonly called uræmic. The author claims that this hypothesis is confirmed by the results of lumbar puncture. He found that early in the disease there was a great increase of intrathecal pressure, but at a later stage this was not so, and he considers that this is explained by the occlusion of the arachnoid foramina occasioned by the increased pressure. This explanation is perhaps open to criticism; if the intracranial conditions are as described it might be expected that lumbar puncture would be a highly dangerous procedure, and the author might be considered fortunate in not having to record cases of fatal termination through impaction of the pressure-cone. In the summary it is stated that lumbar puncture should be used guardedly for this reason. Treatment of this type of nephritis was directed by Dr Blackfan towards the reduction of the intracranial pressure, and was found to be effective in relieving the cerebral symptoms Intravenous injection of a 1 per cent solution of magnesium sulphate was found to reduce the arterial pressure, and presumably the intracranial pressure, considerably and immediately; this was accompanied by the administration of large doses of the same salt by the mouth and rectum, the intravenous injection being repeated, if necessary, on the following day

INFLUENZA IN SCOTLAND

IN the Scottish Registrar-General's return for the quarter ending June 30th, 1926, there is shown a somewhat striking increase in the deaths from influenza The total number of deaths for the quarter was 797, as against 198 for the corresponding quarter of 1925 The contrast invites examination Of the 797 cases, 515—that is about 64 per cent—occurred in the 16 principal towns But the distribution over the months was unequal In the month of April there occurred 330 deaths, in May 68, in June 17 When we analyse this still further in the light of the weekly returns we find that in the four successive weeks of April, the deaths from influenza were 81, 115, 80, 54 In May the figures tapered off as follows 27, 25, 17, 15, 6 In June they were 6, 2, 3, 5 Thus, of the total town deaths (515) about 64 per cent occurred in the month of April It may, therefore, be taken that of the deaths for all Scotland (797) the great majority occurred in the first three weeks of April This is rather a striking fact As a rule infectious diseases sink to their lowest for a period in April Obviously influenza has, this year at least, not followed the rule If, however, we look back a little, the increase, though great, is not so sudden as it looks There were 40 deaths from influenza in January, 35 in February, and 100 in March The epidemic was on the rise If we look back to 1924 we find that the deaths in the second quarter of that year were 767 Of these 224 occurred in the principal towns, and of these again 153 occurred in April It may be assumed that approximately the same proportion occurred in the other areas of Scotland The question, therefore, arises whether we have not here in 1926 the peak of another small wave of influenza Dr Brownlee, in his analysis of influenza epidemics, finds that in the minor waves between the great pandemics there is usually an interval of 33 weeks In 1924 the total deaths from influenza were 2490 In 1925 they fell to 1246 In 1924, in the principal towns, the lowest number of deaths occurred in August But as in 1925 there were 1246 deaths, the way is not quite clear for suggesting that the 33 weeks period has been verified We seem still to be living among the wavelets of the 1918 epidemic In the years 1918–25 the Scottish deaths from influenza were 11,111, 7215, 1339, 1330, 3706, 531, 2490, 1246 The great drop in 1923 suggests that there must be some change in the method of record Otherwise the stream of cases has been unbroken In the light of this sequence, and particularly in the light of the facts for 1924, the sudden increase of deaths in April, 1926, does not appear so exceptional But deaths from influenza are not the whole case Deaths from pneumonia and influenzal pneumonia are equally striking For the second quarter of the year 1924 the deaths from pneumonia and influenzal pneumonia were 1568, in 1925 they were 1142, in 1926 they were 1536 The weekly returns for the principal towns show that the great incidence, as might be expected, is in the cities The respiratory deaths as a whole show an increase in April, May, and June, corresponding to the increase in influenza Thus, in April there were 895 deaths, in May 465, in June 274, and in July 245 It is clear that the influenza outburst was associated with an outburst of pneumonia, influenzal pneumonia, and bronchitis The relations between influenza and the pneumonias are still difficult to define and the question arises whether some of these outbreaks may not be pneumonia complicated by influenza rather than influenza complicated by pneumonia It is certain that where influenza intervenes the pneumonia death-rate rises Whether this applies to all "types" of pneumonia is still for investigation From 1918 onwards, as in influenza, the stream of the pneumonias goes on unbroken At least in some areas pneumonia continues to increase Pneumonia and influenza seem to vary more or less together

SYMBIOSIS

SYMBIOSIS is always a curious and interesting topic. The word has been used in a variety of meanings, and has not infrequently been the peg on which extravagant imagination and bad technique have hung their confusing products In a limited pathological sense it is often important to know, and generally difficult to determine, whether the total action of two infecting organisms is the sum of their separate actions, or whether something additional is achieved when they act jointly The streptococcal invasion of a tuberculous lung to which the symptoms of phthisis are so largely due, or the purification of a stinking wound by the "Reading" bacillus are hardly cases of symbiosis properly so-called, but they are examples of a large group of occurrences round which Dr Aldo Castellani writes an interesting article in the *Journal of the American Medical Association* (1926, lxxxvii, 15) His original observations fall under two headings In the first place he reviews a number of cases where two organisms together will do more in a test-tube than the sum of their separate actions Thus the typhoid bacillus produces acid and no gas when grown in mannite or maltose, Morgan's bacillus does not ferment either substance, a mixture of the two bacilli ferments both carbohydrates with the production of acid and gas Other examples of the same kind were found in studying the separate and combined actions of the yeasts and bacilli of which ordinary commercial yeast is made up In the second place he cites three examples of clinical diseases where two organisms are concerned Trichomycosis nigra is a disease of axillary and pubic hair, in which small black nodules on the hairs are made up of a fungus (*Nocardia tenuis*) and a pigment-producing coccus (*Micrococcus nigrescens*) In trichomycosis rubra the same fungus is associated with a coccus which produces red pigment. In a stomatitis, clinically clearly distinct from thrush, he has found a yeast-like fungus (*Cryptococcus graciloides*) with a bacillus (*B vermiculoides*) It is obviously difficult in these cases of surface lesions to be sure, or to furnish clear proof, that some associated action is going on which is an essential feature of the disease The facts are, however, suggestive, and the ideas in Dr Castellani's mind are worth consideration

LEAGUE OF MERCY —In 1925 the League gave £15,000 to King Edward's Fund, making a total so contributed of £383,000 since the League was started in 1899 In addition £9901 was granted to extra metropolitan hospitals The total amount that has been distributed to hospitals now reaches £457,732

GERMAN ASSOCIATION OF UROLOGY —This Association will meet from Sept 30th to Oct 2nd in Vienna A very full programme has been arranged On Sept 30th the subject of Pain and how to Combat it in Urology will be discussed in the morning, while for the afternoon session 42 communications on the Pathology of the Kidney and the Ureter have been offered On Oct 1st in the morning the Pathology, Pharmacology, and Therapy of Anuria will be the subject of discussion, while in the afternoon, after a business meeting, the Association will receive communications on the pathology of the bladder and prostate On Oct 2nd the morning will be devoted to a discussion on malignant growths of the bladder, and the afternoon to one on the pathology of the urethra and genital passages Among those taking part are V Blum and F Necker (Vienna), Georges Luys (Paris), H Wildbolz (Berne), O S Lowsley (New York), L Casper (Berlin) Further information may be obtained from the President of the Association, Prof V Blum, Alserstrasse 43, Vienna VIII

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CLXXXVIII.—THE MEDICAL TREATMENT OF CHRONIC DIARRHŒA.

I.—INVESTIGATION OF THE CASE.[1]

THE management of a case of chronic diarrhœa must be based on a clear appreciation of the cause of the symptom. Palliative treatment with bismuth chalk, or opium, is rarely indicated and never satisfactory. Whether in a persistent or recurrent form diarrhœa may be the leading complaint in so wide a group of diseases that an enumeration of these, together with a brief account of their main clinical features must be accepted as a proper preliminary to any discussion of therapeutics. An enumeration of the more common types of chronic diarrhœa is appended. As the diagnostic importance of these two observations is very great, yet not always recognised, it is also well to insist that *no case of chronic diarrhœa can be regarded as having had a full clinical examination,* unless this has included (1) *a digital examination of the rectum, and* (2) *a naked-eye inspection of the stools.* Some cases will require a more searching inquiry with laboratory or other accessory diagnostic methods.

Diarrhœa of Gastric Origin.

This is a condition dependent on gastric achylia—a painless diarrhœa occurring especially in the early morning before breakfast and after meals. There are usually two to four actions per diem, occasionally six to eight. Stools are soft and light brown. No blood or mucus is present, and abdominal and rectal examinations are negative. Occasional associated symptoms are (1) acne rosacea and morning nausea when the achylia is due to chronic gastritis, (2) pernicious anæmia. The diarrhœa may precede the development of the anæmia by several years. Test-meal shows absence of free hydrochloric acid. Microscopic examination of stools may show excess of undigested meat fibres and other evidence of alimentary "hurry." X ray after barium meal shows "gastric hurry."

Diarrhœa of Colonic Origin.

This group includes cases associated with colonic and rectal carcinoma, chronic ulcerative colitis, the dysenteries, spurious rectal and colonic diarrhœas, and certain rarer forms.

(1) *Colonic and Rectal Carcinoma.*—Urgency pain, and loss of weight are associated symptoms. Blood, pus, and mucus are present in stools, not always macroscopic, but usually more conspicuous the lower the situation of the growth. There are from three to four, up to 20 or more actions a day—the lower the lesion the greater the frequency. Sometimes diarrhœa and constipation alternate. Diagnosis is confirmed by digital or sigmoidoscopic examination, laboratory examination of stools, and X rays with barium enema.

(2) *Chronic Ulcerative Colitis* (non-specific), and *Chronic Bacillary Dysentery.*—These are usually associated with colonic flatulence and pain, frequent fluid stools up to ten or more per diem, with blood and mucus, anæmia, loss of weight, and tenderness along descending colon. Diagnosis is confirmed by sigmoidoscopy which reveals a red, universally unhealthy, granular mucosa, flecked with muco-pus, bleeding easily superficial ulceration, and in severe cases, deeper irregular ulcers. Diagnosis of bacillary dysentery may occasionally be decided by recovery of the organism from direct swabbings through the sigmoidoscope or by serological reactions with the patient's serum against known types.

(3) *Chronic Amœbic Dysentery.*—In most cases, but not all, there is a history of residence in the tropics; frequently a mild diarrhœa with little or no pain and only slight disturbance of general health occurs. Macroscopic blood and mucus are not always noticed by patients. Sometimes there is tenderness over cæcum, ascending colon, or edge of liver. Diagnosis is confirmed by sigmoidoscopy which shows small clear-cut rounded ulcers appearing as craters on small elevations, the intervening mucosa being healthy. Microscopic examination shows red cells, and, perhaps, amœbæ or cysts. Sigmoidoscope sometimes confirms when laboratory reports are negative.

(4) *Spurious Rectal and Colonic Diarrhœa* may be (*a*) due to *fæcal retention* or impaction in old or feeble subjects, when rectal pain or intermittent constipation and diarrhœa may be present, or a fæcal accumulation may be revealed on rectal examination; or (*b*) *muco-membranous colitis,* in which there are attacks of so-called "diarrhœa" alternating with periods of constipation, colonic pain, worse after defæcation, and passage of scybalous fragments and copious mucous shreds and casts. In these cases the colon is hyper-irritable and often easily palpable owing to spasmodic contraction. Commonly a history of abuse of purgatives and the well-known neuropathic associations may be obtained. Blood is rarely present. Sigmoidoscopy shows a mucosa normal or redder than normal, but not granular or ulcerated.

(5) *Rarer forms* of chronic intestinal diarrhœa include those associated with the terminal colitis of *Bright's disease* and with *amyloid disease.*

Diarrhœa consequent upon Diseases of the Absorptive System.

(1) *Tabes mesenterica* occurs generally in children or young adults. the mild cases reporting slight chronic diarrhœa with pale or yellow motions, vague abdominal pains referred to both iliac fossæ, slight afternoon pyrexia, and general symptoms suggestive of tuberculous infection. the more serious cases showing copious bulky evacuations, pale. greasy, and porridgy, stunting of growth, abdominal enlargement, slight anæmia, and sometimes tetany. Stools contain excess of fats in the form of soaps and fatty acids.

(2) In *cœliac disease,* pale, bulky stools as above with abdominal enlargement and infantilism are found. This disease is confined to early childhood.

(3) In *sprue* there is always a history of residence in the tropics, abdominal enlargement, sore tongue, great wasting, copious pale, fatty and frothy stools. and frequently an anæmia resembling Addison's (pernicious) anæmia.

Chronic Diarrhœa from Tuberculosis of the Small Bowel.

This is usually a late complication of chronic pulmonary tuberculosis or grave abdominal tuberculosis. Frequency of stools is variable. commonly four to six in the day or more when ulceration extends to colon. Pain around the navel and in right iliac fossa, tenderness in right iliac fossa. and post-prandial diarrhœa, especially after hot drinks, are found. Stools are usually semi-fluid and light in colour, rarely showing visible blood, but giving positive chemical and spectroscopic tests. With associated glandular involvement there may be chalky stools, frothing under a stream of water, and showing excess of fatty acids and soaps under the microscope.

Other Forms.

Infective or irritative diarrhœa accompanying *chronic cholecystitis* and *appendicitis* is usually slight, intermittent rather than chronic, and associated with the local or dyspeptic symptoms and signs of these diseases.

In *pancreatic diarrhœa* the stools are copious, pale, and oily (steatorrhœa), congealing on a cold surface or caking on the top of a liquid motion. There is serious loss of weight. Fat globules are present;

---

[1] An article in this series by Dr. Ryle on Chronic Diarrhœa: the Management of the Case will appear in THE LANCET next week.

also starch and meat fibres The diastase test or glycosuria may give further evidence of impaired pancreatic function

Nervous diarrhœa may be (*a*) a visceral neurosis expressing anxiety, always worse on certain occasions, and especially before public functions As the uncertainty associated with all forms of chronic diarrhœa itself creates anxiety it is well to recognise that a nervous diarrhœa may have had its origin in some other disturbance of function, (*b*) an accompaniment of Graves's disease

Diarrhœa due to excessive ingestion of carbohydrate is usually very mild—one to three soft actions a day with much intestinal flatulence It accompanies an excessively starchy diet and deficient exercise French authors lay more stress upon this condition than is usual in this country, and describe a variety with frothy, gaseous motions

Diarrhœa following gastro-enterostomy may manifest itself in (*a*) benign, or in (*b*) grave form. (*a*) In the benign form a too-patent stoma is associated with rapid evacuation of the stomach and overloading and irritation of the small bowel Stools are light in colour There may be loss of weight The microscope shows poor digestion of meat fibres and fats, owing to precipitate passage of the gastric chyme (*b*) The grave form is associated with gastro-colic or jejuno-colic fistula; serious loss of weight, pain, eructations of foul gas, and sometimes vomiting of fæces may occur The diarrhœa may be very profuse Confirm by X ray, which may show tenderness or other evidence of ulceration near the stoma, and fractional test-meal, which may recover colonic matter from the stomach Occult blood is found in stools

The treatment in some of these types, notably diarrhœa due to carcinoma, a terminal colitis, tuberculosis of the small bowel, cholecystitis and appendicitis, Graves's disease, and gastro-colic fistula, is either that of the primary disease, or surgical, or purely palliative, and will not here be considered The management of cases of the other types will be outlined in Part II of the present article

MEDICINE AND THE LAW

Workmen's Compensation Lead Poisoning Liability of Successive Employers

In 1906, as is well known, Parliament extended the system of workmen's compensation to illnesses due to industrial diseases such as lead poisoning Section 8 of the 1906 Act had the effect of treating as an accident something which would not ordinarily be treated as an accident—namely, the occurrence of a progressive occupational disease at the point at which the workman is disabled by it It was clear that this new principle would operate arbitrarily against a particular employer where the occupational disease had already set in while the man was in the service of previous employers Parliament, therefore, made provision for exacting contributions from previous employers as well as dealing with the liability of the final employer In the latter connexion Section 8 used significant language to emphasise the requirement of an immediate relationship between the time of the employment and the time of the industrial disease If the workman "*at or immediately before the date of the disablement or suspension*" was employed in one of the specified processes, the disease 'shall be deemed to have been due to the nature of that employment unless the employer proves the contrary " In other words, if the occupation is one which can give rise to the industrial disease, then there is a presumption in favour of the workman that the occupation did in fact give rise to the disease But the presumption is not absolute, more than one workman has lost his claim for compensation on that account in circumstances which deserve examination Those words, "at or immediately before the date of the disablement or suspension" are important If there has been an interval between the employment and the disablement or suspension, then the presumption against the employer does not arise Twelve years ago there was a case (Dean *v* Rubian Art Pottery, Ltd, 1914, 2 K B, p 213) in which the workman had been employed down to April 18th and died of lead poisoning on May 15th It was held that the comparatively short interval between these two dates was long enough to upset the presumption This decision was followed early in the present year by the Court of Appeal in Blatchford *v* Staddon and Founds where the interval was a good deal longer Blatchford was 53 years old, he had served in the navy until 1918 as a painter, and had contracted lead poisoning during that period of service the symptom of drop-wrist having manifested itself His subsequent employment as a painter under various employers was as follows He got work in 1920 and for the whole of 1923 and the first half of 1924 From July to mid-September he was out of work; from then till mid-October he had a job, finally, after ten days' unemployment, he got work with fresh employers (Messrs Staddon and Founds, the respondents in the action) from Oct 23rd, 1924, till Dec 12th, when he left because of illness On July 13th, 1925, a certifying surgeon certified that Blatchford was then suffering from lead poisoning This date was important because, under Section 8 (4) of the Act, unless the certifying surgeon can fix some date as that of the commencement of the disease, the date of disablement is to be construed as being the date when he gives the certificate The result was that there was a seven months' interval between Dec 12th, 1924, the date of employment, and July 13th, 1925, the date of disablement Because of this interval Blatchford lost the benefit of the presumption that his lead poisoning was due to the nature of his employment with Messrs Staddon and Founds Having lost on this point as a matter of law, he could still succeed as a matter of fact if he could show that his lead poisoning was caused, or aggravated, or accelerated by his employment under Messrs Staddon and Founds, but here the county court judge decided against him The Court of Appeal said there was evidence on which the county court judge could have come to the conclusion which he reached, though perhaps not every judge would have come to it in that particular set of circumstances The result was that Blatchford lost his application and lost his appeal He had had, like any other plaintiff, to establish his case to the satisfaction of the county court judge, and the case which he had had to establish was that his disease was due to the nature of his employment under the employers whom he was suing and not that it was due to similar employment under other employers

It was Blatchford's misfortune that his medical advisers were slow in diagnosing his disease as lead poisoning—an opinion which his medical and occupational history, if known, would have readily suggested His panel doctor diagnosed his illness in December, 1924, as "general debility affecting the heart," and, according to the statement made in court of the facts of the case, it was not till the following June that the doctor attributed the illness to lead poisoning The evidence of the effect of Blatchford's employment under the respondents was not put very high His panel doctor said no more than that if Blatchford had lead in his system before, his three months with the respondents might have aggravated it On the other hand one of the certifying surgeons said that if Blatchford had not been employed at all in that final November and December, "the symptoms would nevertheless have shown themselves and he would have been disabled as he now is"

Section 8 of the Workmen's Compensation Act of 1906 has, as Lord Justice Scrutton remarked, been said to be the most obscure and complicated section in the Act. It was repealed with the rest of that Act when the consolidating Workmen's Compensation Act was passed in 1925, but it reappears in that Act in all its original obscurity and complication. It may be that Parliament really meant that if the applicant is a painter and suffers from lead poisoning, and if painting may produce lead poisoning, and if the applicant was last employed by the respondents, then the respondents must pay him compensation (whether or not the last employment had anything to do with creating or accelerating his lead poisoning) and get what contribution they can from his previous employer. But the Court of Appeal had already decided in Dean's case in 1914 that this was at any rate not what Parliament said. If the Court of Appeal is wrong upon this point, it can be overruled only by taking the matter to the House of Lords.

Dangerous Drugs Acts Regulations: Non-disclosure of Concurrent Treatment

The Regulations made last July by the Home Office under the Dangerous Drugs Acts were designed to restrict inter alia the possession of drugs by a person who is obtaining prescriptions from several doctors concurrently. Prosecutions for infraction of these Regulations are already taking place. On Sept 2nd a defendant was charged at the Westminster police-court with having been in possession on August 23rd of a quantity of heroin prescribed by a doctor without making disclosure that he was being attended by other medical practitioners for the same class of treatment. The accused stated that he had acted in ignorance of the recent Regulations. He said he had been under treatment from an acting police doctor and that, in the absence of the latter, he consulted another practitioner. The charges apparently had reference also to a third doctor, but no medical evidence was given at this stage of the proceedings. The accused did not accept the suggestion of the prosecution that he should plead guilty and have the case dealt with summarily. He was, therefore, remanded and presumably the doctors concerned will be required to give evidence. The difficulty of professional conduct which arises under the new Regulations, when a doctor is required to appear against his own patient and to disclose details of treatment, was not unforeseen by the committee which investigated the methods of restricting the supply of drugs to addicts. The legal view (that a doctor if called upon by the court to give evidence of this nature, cannot refuse on the ground that the communication was privileged) is well known and can in this particular connexion be defended as being in the best interests of the patient. Presumably the offence, if an offence has been committed, is established if the medical practitioners formally identify their prescriptions and state (if such is the case) that they were not informed by the patient that he was under treatment by another doctor. The first point to be proved in the case is the possession of the drug, which is a matter of police evidence, the non-disclosure by patient to doctor is the next step. The police might in these cases be in a position to prove simultaneous supply and the fact that prescriptions had been obtained from more than one doctor at a time by calling as witnesses the persons who made up the prescriptions and handed the drugs over the counter. The chemist can say that he supplied the drug on the faith of the prescription but he cannot prove the signature or initials at the foot of a prescription, still less of course can he prove what the patient said or did not say to the doctor.

Prosecutions of this kind should be given the utmost publicity. The course of action which the Regulations require is one of which many defendants are likely to plead ignorance. Everyone according to the English legal principle, is supposed to know the law or to put the doctrine in a slightly milder form no one is entitled to plead ignorance of the law. Genuine ignorance of the new Regulations will be no defence to a charge thereunder though it may be an element tending to mitigate sentence.

METROPOLITAN ASYLUMS BOARD

MORE SAMPLES OF THE YEAR'S WORK

A LARGE number of scientific papers are included in the medical section of the annual report for 1925–26 of the Metropolitan Asylums Board, whose general scope has already been indicated.[1] Two of these papers were summarised in our issue of Sept 4th. These and the additional summaries which follow may serve to give an idea of the wide scope and progressive character of the Board's medical work.

HOSPITAL SCHOOLS

When day-schools for the physically defective were instituted it was apparent that the time-table and curriculum of the ordinary elementary school could not be used without modification. Special regulations were issued by the Board of Education which required that a school shall hold not less than 400 meetings in the year, each meeting lasting, as a rule, not more than two and a half hours, and providing for at least one and a half hours of secular instruction, apart from any time given to registration and recreation. The curriculum should include such "ordinary subjects" as English (speaking, reading, literature, writing, composition, and recitation), arithmetic, the knowledge of common things (nature study and observation lessons), history, geography, and singing. Not less than six hours of manual instruction must be given weekly. A grant, based on average attendance, is payable to managers of special schools not provided by authorities. The grant is £15 10*s* for each unit of average attendance at a certified boarding school, increased to £24 10*s*. if it is an open-air boarding school for children suffering from tuberculosis, debility or pre-tuberculous conditions.

In his report on teaching arrangements at hospital schools Dr W. T Gordon Pugh summarises the relevant regulations and compares the position of special and hospital schools. The regulations for special schools, he says, were applied to hospital schools without modification, save the insertion of a note that in schools where children were taught in bed the teaching must often be mainly individual in character, and the time-table should be planned to provide suitable occupation for sick children. In some instances little or no difficulty arises. This is so when the number of patients in a ward approximates to that usually accommodated in a school class-room; when, through a high average age of the children, interference with the teaching arrangements by quarantine is only very occasional. and when the medical or nursing treatment necessary during school hours is practically negligible. In other institutions on the contrary, it is impossible to conform with the regulations without undue expenditure. Difficulty occurs, for example, when the wards are small and the potential pupils in them considerably fewer than the number laid down for each teacher in the regulations. Again, if change of patients is relatively frequent, particularly if young children are received there is a greater liability to the introduction of infection with consequent quarantine. Also it is impossible in many cases to arrange for the full school hours when the hospital provides forms of treatment which can only be given adequately and economically in special departments at a distance from the wards—e g light treatment, medical electricity massage gymnastics application of radium and to a less extent attention by operating surgeon dentist oculist and splint maker. In large institutions the transport of patients for these purposes still further consumes time. Thus the more varied a hospital's activities the more difficult it is to conform in exact detail with regulations originally designed to suit a day-school.

Dr Pugh gives a short account of the arrangements at three full-time hospital schools—St Vincent's

---

[1] THE LANCET August 21st p 392

Orthopædic Hospital at Pinner, the Liverpool Hospital for Children at Leasowe, and Princess Mary's Hospital, Margate—and concludes with a description of the arrangements at Queen Mary's Hospital, of which he is medical superintendent Several years ago, he says, the subject of education received careful consideration at this general hospital for children, where the patients vary in age from a few months to 16 years, and where all the difficulties mentioned above as liable to occur in the case of full-time hospital schools actually prevail The accommodation of a ward is 16, and of a verandah 15, and that an attempt to teach the patients of both together was not a success If all the regulations of the Board of Education were to be carried out, it was estimated that at least 40 assistant teachers would be required to work wards and verandahs as separate units In view of the medical difficulties already referred to, it was felt that the great expenditure which this would entail was not justifiable Since the hospital and school are provided by a Poor-law authority, no grant is payable by the Board of Education The principal features of the scheme which was eventually approved are —

(*a*) A teacher takes two classes, each of which contains usually 12–16 pupils—i e , she takes the ward patients from 9 10 to 10 25 A M. and from 1 30 to 2 45 P M , and the verandah patients from 10 35 to 12 noon and 2 45 to 3 55 P M On alternate days this arrangement is reversed , this allows of the medical officers, masseuses, and sisters performing their duties without interfering at all with the teaching

(*b*) The Dalton system of teaching has been adopted in a modified form

(*c*) Nearly as much time is given to "ordinary subjects" as in the average cripples' school, for it is felt that these are of paramount importance An exception has been made in the case of singing, to which less time is allocated

(*d*) The time allowed for manual instruction has been reduced This, however, is to some extent compensated for by the smallness of the unit allowing more individual attention, besides which suitable children are encouraged to continue their handwork out of school hours As most of the pupils are in bed, and thus no real vocational handwork is possible, the time allowed for the latter at ordinary schools for physically defective children has not to be provided for

(*e*) Physical exercise is undertaken out of school hours by trained medical gymnasts, one of whom works in connexion with each block for recumbent patients, and by the attendants in the ambulant boys' wards

(*f*) Recreation and games do not occupy a place in the time-table, as it is not essential that the organisation of these should be undertaken by teachers The patients play ordinary games under the supervision of nurses or attendants , chess and draughts matches take place between the senior wards , there are troops of scouts and guides , entertainments in the form of concerts, plays, conjuring or cinema are given almost weekly during the autumn and winter months , and many of the patients, both recumbent and ambulant, attend cricket and lawn tennis matches during the summer There is a well-filled library Every ward, too, is fitted with an aerial, and two loud-speaker valve sets and a number of crystal sets are in use for the patients' entertainment , it is likely that the wireless will prove of considerable educational value to older children who stay for a long period in hospital

This scheme, says Dr Pugh, has allowed the recommendations of the Board of Education to be reasonably closely followed in essential subjects The teaching staff numbers 25, which would suffice at a day-school for the physically defective for an average attendance of 615 On an average there are 572 on the registers, and it is probable that, through the close individual attention which the smallness of the classes allows, and the regular attendance which is ensured, the general educational benefit received by these pupils at least equals that which is received by members of the larger classes of the ordinary day-school for the physically defective, notwithstanding the shorter duration of the meetings

The following table is given by Dr Pugh to show the hours per week allotted to the teaching of the secular subjects included in the curriculum of the Board of Education in the schools described In addition, time is allocated to scripture in each school —

Hours allotted to—	Two P D day schools		Hospital schools			
	A	B	St Vincent's	Liver pool	Princess Mary's	Queen Mary's
Ordinary subjects	8¼	10	8¼	10	9½	7¾
Handwork	6¼*	7½*	6	6½	6	3½
Physical exercises	2½	2	½	1	1	1¼

* Including craft work.

BALNEOTHERAPY FOR SURGICAL TUBERCULOSIS

An institution at Cannes where sea bathing had an important place in the treatment of children suffering from tuberculosis, joint and bone disease, was recently described in our columns,[1] and the advantages of balneotherapy are well recognised In this country, however, strong winds, rough seas and unsuitability of tides make organised and continuous bathing difficult for many children, and any bathing at all may be impracticable for those who are so crippled that they have to wear splints or jackets At Millfield, Rustington, Sussex, steps have been taken to institute a system of spraying the children with sea water while protected from the weather, and a description of the procedure is given by the visiting medical officer Dr C E Last Advantage was taken of the natural protection of a high hedge which separates the grounds of Millfield from the shore and which runs east and west Sheltered compartments were made on both sides of this hedge by using 6 feet high wattle fencing, the compartments on the north side being used during a southerly wind, and those on the south side when the wind is northerly A large raised tank has been erected close to the hedge, and this is filled with sea water in a few minutes by means of a hand-operated suction and force pump A two-way pipe leads out of the tank, one to the north side of the hedge and the other to the south, and a sprayer is attached to one of them according to which side is being used for operations According to their condition and capabilities, some of the children stand on wooden gratings for spraying, some sit, and others who normally wear splints or jackets are laid down on the beach After spraying, their feet are put in a trough of hot water and they are rubbed down and dressed before leaving the shelters Operations were begun on May 14th and discontinued on Oct 10th, 1925 , during this period over 2000 sprayings were recorded, and it will be interesting to hear more of the results of this experiment

TREATMENT OF RINGWORM

At the Goldie Leigh Homes at Abbey Wood the Board has departments for the treatment of skin diseases and of ringworm During 1925 372 cases of ringworm were admitted, all of which were caused by the common fungus of ringworm in children—the *Microsporon audouini*—except four in which the large-spored *Trichophyton endothrix* was responsible. In the great majority of cases the ringworm was entirely confined to the scalp In a few, patches were also present on the glabrous skin, and in several cases the glabrous skin alone was involved Dr J M H MacLeod, consultant physician for skin diseases, points out that a certain number of cases are still being admitted which have been under treatment for varying periods with irritating antiparasitic applications, which have produced so much inflammation that it has been necessary to delay the exposure to the X rays, sometimes for weeks, to enable the inflammation to subside under soothing treatment before applying the rays The number of such cases, however, is fewer than in the previous year and he hopes "that in time it will be realised that the only effective treatment for ringworm of the scalp is the X rays and that the less done to the cases before they are sent up to be rayed the better" The new apparatus and method of dosage, described in detail in the report for 1924, continue to give satisfactory results, and during the year there has been no case of X ray dermatitis, followed by permanent baldness, and only one case had to be partially re-rayed owing to insufficient depilation of the hair The couch for restraining refractory cases is also proving adequate, and has rendered it possible to deal with many cases which otherwise could not have been rayed safely It has also allowed of the treatment of a number of infants between 1 and 2 years of age without subsequent ill-effects

INDIA

(FROM OUR OWN CORRESPONDENT)

Tuberculosis in Calcutta

DURING 1924 the total number of deaths in Greater Calcutta was 30,822, which is equivalent to a mortality of nearly 30 per 1000 for the city This figure was slightly higher than in the previous year, and an unsatisfactory feature was a rise in the number of deaths from tuberculosis In Calcutta nearly all deaths from this disease are due to the pulmonary form, and the medical officer of health, Dr H M Crake, thinks that the rarity of surgical tuberculosis (some 6 per cent only of deaths from tubercle being due to this variety) is a consequence of the fact that Bengal cattle are rarely consumptive Tuberculosis in India appears to run a very rapid course, possibly for this reason signs of old infection are comparatively uncommon amongst Indians. The death-rate varies in different classes of the community Amongst Mahommedans in 1924 it was 3 per 1000, amongst Hindoos, 2 3, and amongst Indian Christians, who are few in number, it was 3 8 Far more striking, however, was the variation in mortality at different ages and in the two sexes For boys between 10 and 15 years old the death-rate was only 0 45 per 1000, and for girls 2 2, but after this age there was a remarkable rise in the female mortality From 15 to 20 years it was 6 6, and from 20 to 30 6 4 per 1000, and in the fourth quinquennium of life six times as many girls died of tuberculosis as boys Dr Crake attributes this high death-rate to the retention of the purdah system in the densely populated gulleys of a congested city, where it is difficult to secure absolute privacy without shutting out the light and air The zenana is usually in the inner part of the house, ill lighted and ill ventilated, but effectually screened from observation, and in these unhealthy surroundings girls and young women are subjected, whilst still immature, to repeated pregnancies and long periods of lactation Probably there are 10,000 cases of tuberculosis in Calcutta, and hardly any precautions are taken against the spread of infection Thousands of consumptives are constantly spitting all over the place, and those who have to carry out the anti-tuberculosis scheme now approved by the Health Committee have a big task before them

The Reorganisation of Public Health Activities in Bombay

The report of a committee appointed by the Government of Bombay to consider the question of the reorganisation of the Public Health Department and the transfer of control of medical, vaccination, and veterinary staffs to district local boards, has been issued They recommend that the control of the existing staff of the subordinate medical service should remain as at present, but that all new appointments should be left entirely to local boards, who should receive grants-in-aid to enable them to take over this responsibility The result of the recommendation would be the ultimate assumption of control of the whole subordinate medical staff by the district local boards As to recruitment, the committee hold that as vacancies occur they should be filled from doctors registered by the Bombay Medical Council, subject to the approval of the Surgeon-General, at a minimum salary of 50 rupees per mensem Under the scheme outlined the civil surgeon would continue to inspect grant-in-aid dispensaries and his advice on technical and professional matters would be accepted by the local boards The transfer of control of the veterinary staff is not recommended but it is suggested that Government grants for the maintenance of veterinary dispensaries should be increased As to the vaccination staff, their future is considered in connexion with the desirability of reorganising the public health department It is the duty of district local boards to provide for medical relief and to undertake measures for the health, safety, and convenience of the public, and it is desirable that they should take in hand the sanitation of the districts The committee consider it necessary that these bodies should appoint district health officers with sufficient establishment under them They recommend that a district health staff should be appointed consisting of a health officer, inspectors, and sub-inspectors for each district according to its size and population, and make detailed suggestions as to the proportion of the cost of this scheme that should be borne by the Government They consider it necessary to retain the existing officers of the Public Health Department for advising and guiding the new health staff appointed by the boards and recommend that the officers of the Public Health Department should continue to exercise their present powers of professional inspection and advice They are of opinion that the appointment of the health staff by local boards should be made optional They have also considered the question of the transfer of the function of maintaining vital statistics to district local boards, and consider it desirable that after the boards have appointed district health officers they should have control over the maintenance of vital statistics

Vaccination in Bengal.

In the year 1924–25 over 2,661,000 persons were vaccinated in Bengal against small-pox The primary vaccinations increased by more than 4 per cent and revaccinations by 115 per cent, the average number of operations performed by each vaccinator in rural and municipal areas being 1492 Some 293,000 vaccinations were done in Calcutta The report presented by Major A D Stewart records that the number of infants successfully vaccinated throughout the Presidency per 1000 of the population was 275 as compared with 262 in the previous year Of the total of about 1,112 000 infants available for vaccination over 300,000 were dealt with and in some districts half the available infants were thus protected

LONDON HOMŒOPATHIC HOSPITAL.—This hospital, which had been closed for alterations and redecorations, was reopened on Sept 1st The dispensary has been enlarged and re-equipped and a sunlight lamp has been installed in the Mechano-Therapy Department The new works have cost £10,000, most of which has yet to be raised

ENLARGEMENT OF CHARING CROSS HOSPITAL.—The recent purchase of the adjoining premises of the Royal Westminster Ophthalmic Hospital will involve the largest extension scheme in the history of Charing Cross Hospital The institution has long been so badly cramped for room that many patients have had to be refused because there were no available beds and no space for increasing the number An additional floor was added as a children's department which reached the permissible limits of height, while the basement and sub-basement are already utilised The Ophthalmic Hospital building is not to be rebuilt, but will be so altered and adapted that it will provide a larger nose, throat, and ear clinic, more beds for heart cases, an extensive department for skin troubles, and a children's gymnasium and permit of other developments The cost of purchase and conversion will be £100 000 and a special appeal for that amount has been issued The hospital has no debt and has paid its way since 1915

THE MEDICAL REGISTER UNTRACEABLE PRACTITIONERS IN 1926

WE are requested by the Registrar of the General Medical Council to publish the following list of medical practitioners who have not replied to his inquiries as to the accuracy of their addresses Anyone who finds his or her name included in this list should communicate immediately with the Registrar of the General Medical Council, 44, Hallam-street, Portland-place, London, W 1, otherwise the name will be omitted from the next issue of the Medical Register

Public Health Services.

Safeguarding of Certification Forms

In a circular addressed to insurance committees the Minister of Health states that cases still come to light in which sickness or disablement benefit has been fraudulently obtained by means of forged medical certificates, the forms having been stolen from practitioners' surgeries Practitioners are reminded that books of certificate forms should be kept under conditions which will prevent their falling into the hands of unauthorised persons A warning to this effect is to be printed on the covers of the first batch of certificate books issued to practitioners when they first join the medical list, and on the first batch of books issued to all insurance practitioners at the commencement of each year

REPORTS OF MEDICAL OFFICERS OF HEALTH

The following are some of the statistics for 1925 of six county boroughs Three of them appear in a list in the Brighton report of the 11 densely populated towns of England—viz , West Ham with a density of 64 per acre, Brighton with 53 (without taking the foreshore into account), and East Ham with 43

Name of county borough	Estimated mid-year population (R G)	Birth rate	Death rates per 1000 of the population					Death-rates per 1000 births	
			All causes	Tuberculosis	Cancer	Resp diseases with influenza	Heart disease	Infant mortality	Maternal mort from childbirth
West Ham	318,500	22 0	10 7	1 27	1 12	2 4	1 3	66	2 8
East Ham	147,200	17 3	10 2*	1 07	1 36	2 0	1 4	53	3 1
Brighton	137,800	15 7	13 4†	1 39	1 72	2 5	1 8	59	3 7
Bournemouth	85,840	13 5	13 8	1 23	2 08	1 9	2 5	53	4 3
Preston	122,900	17 7	14 5	1 19	1 21	3 2	1 4	131	6 0

* Standardised death-rate 10 6 † Standardised death-rate 11 0

West Ham

Dr F Garland Collins reports that during the last five years coordination has been established between his department and the ancillary health services in the district and contiguous areas, also a further linking up of maternity and child welfare, tuberculosis and school medical services He considers that there is one weak link in the chain—namely, the lack of cooperation with the factory medical service In order to cope with the new legislation respecting milk and meat, two additional officers have been appointed, a veterinary surgeon and a meat inspector A sanatorium for children suffering from pulmonary tuberculosis has been a long-felt need, and it is proposed to erect accommodation for 40 children on a site on Langdon Hills belonging to the corporation Other proposals are an open-air swimming bath in West Ham Park and a colony for 500 mental defectives at Ockenden Dagenham Small-pox Hospital is generally in use as a tuberculosis sanatorium It had to be cleared in 1920 in order to make room for a small number of small-pox cases In 1922 the Council arranged with the board of the Orsett Hospital to admit up to 20 cases of small-pox, so as to enable Dagenham Hospital to be in continuous use for tuberculosis, except in the event of a considerable small-pox outbreak Much building is going on in Dagenham, and its population has increased during the last 5 years from 9127 to 38,000 During 1925 a residential open-air school to accommodate 80 boys was opened at Fyfield, near Ongar, Essex, and the children sent to it have derived remarkable benefit, a day open-air school for 60 girls exists inside the borough A large shortage of houses still prevails, and a housing scheme for the erection of 152 four-storied tenement flats is now before the Ministry From 1921 to 1925 the increase of population was 16,140, and the new houses erected numbered only 249 Ninety-six samples of milk were examined bacteriologically, of which 13 contained acid-fast bacilli indistinguishable from the tubercle bacillus It is stated that "appropriate action" was taken in each case Apparently the biological test was not used, since "no case of tuberculous cattle came to the notice of the sanitary authority during the year" The prevalence of diphtheria remains high The fact that it is not wise to delay giving antitoxin until the result of the bacteriological test is known was demonstrated in two of the fatal cases During the latter part of the year some 15 cases of pemphigus neonatorum occurred Six of the cases were born in Queen Mary's Hospital, seven were attended by the Plaistow Maternity Charity, and two were in the practice of a midwife The onset occurred between the fifth and tenth day after birth, with an inflamed lozenge-shaped area in varying situations The area soon became a blister, which was followed in some cases by many others Two of the 15 cases died, the eruption having spread over the whole body and become pustulate No source of infection was established

East Ham

Dr W Benton expresses his regret that the Council have not increased the staff of health visitors, because it is not now possible to superintend the children between infancy and the school age The housing shortage is "the one great outstanding defect" of the borough In the school report a reference is made to the need for improved dental clinic accommodation and for an increased staff Mr C S Neame, the school dentist, points out that the work is being much hampered, and that according to the Board of Education standard there should be at

least four dentists at work in East Ham instead of one as at present The school ophthalmic surgeon, Mr C L Gimblett, refers to the large number of cases of squint "This deformity," he says, "results from the poor development of binocular vision in early life, and should be treated at its first appearance—not by waiting until the child is 5 years old" He also emphasises the need in East Ham for a special school for weakly children

Brighton

Dr Duncan Forbes reports that increasing use is being made of X ray examinations for the diagnosis of tubercle Tuberculin is only used in the form of the Pirquet cuti-reaction for young children The urochromogen reaction is found of value in excluding hopeless cases from sanatorium treatment In a small number of cases artificial pneumothorax has proved of great value, ten patients underwent this treatment during the year The greatest possible use is made of natural sunlight at the sanatorium During a part of the school hours the children wear sun-bathing costumes, and carry out their drills and organised games in the sunshine under the guidance of the teacher During the winter months and on sunless days a small open carbon arc lamp has been in use for several years Provision has also been made at a private light treatment clinic in the town for patients suffering from lupus and tuberculous glands and joints Dr Forbes thinks that the results of light treatment are encouraging, but that the claims made for this treatment in some quarters are extravagant He insists that the crying need for the consumptive is to have work found for him When gardening was tried at the sanatorium the task allotted to the consumptives was monotonous and no payment was made The gardener now in charge recognises that the garden is to be run not for beauty or for gain, but to provide work as required for patients, a pocket money allowance of threepence per hour is made A similar change has been made in the workshop The manual work was formerly too heavy Two hundred pounds' worth of electrically driven machinery has been introduced, and also pocket money allowances These changes have made the patients much more content Dr Forbes would like to see the establishment of municipal work treatment centres An examination of 96 stillbirths resulted in the finding of the *Spirochæta pallida* in 12 of the livers The housing scheme of the corporation comprised the erection of 1116 houses, of which 927 were completed at the end of 1925 There are still a number of cases of overcrowding and of subletting without the use of the necessary conveniences The houses built are sufficient to meet the natural increase of the population, but there is more immigration than emigration in Brighton Two out of the 33 samples of milk examined for tubercle gave a positive result, but visits paid to the farm failed to discover the tuberculous udders In each case cows had been sold between the taking of the sample and the obtaining of the result The by-law for the "humane" slaughter of all animals has been in operation since 1922, during which time nearly 100,000 animals have been slaughtered in the borough The objections of the trade appear to have been withdrawn There were three minor shooting accidents to slaughter-men with some of the pistols used, but there have been no accidents since the introduction of the Cash captive bolt pistol, nor at any time with the R S P C A. cattle killer with free bullet Dr Forbes thinks that three principal points should have been borne in mind when the meat regulations of 1924 were framed First, better meat inspection to prevent the use of carcasses of animals which have suffered from acute illness, secondly, the prevention of the handling of meat by persons who have not washed their hands carefully after defecation This second point has been entirely missed by the framers of the regulations A butcher may have no basin in which to wash his hands after going to the w c, and may make sausages, serve meat, &c, with dangerously polluted hands In the circular letter to the retail trade in Brighton with regard to the meat regulations this point is specially emphasised The third point is that cooked meats are outside the scope of the regulations, although meat which has to be cooked before being eaten is less likely to give rise to trouble than cooked meats

Bournemouth

Dr A D Edwards reports that there were only seven notifications of ophthalmia neonatorum All the cases were mild, but in three instances it was considered advisable to admit mother and child into hospital Fifty-two milk samples were examined for tubercle, but it is not stated whether the examination was biological, or how many gave a positive result In the circular issued with regard to the meat regulations an illustration is given of a suggested type of counter case for cooked meats with glass top, shelves, &c, and marble slate, or hard wood ends Mr R A Cripps, the public analyst, shows that boric acid is still being freely used for sausages The new regulations prohibiting this will come into force on Jan 1st, 1927 Mr Cripps again draws attention to the unnecessary quantity of rice-flour added to shredded suet He considers that when a cheap food is added to an expensive one to make it fit for transit, &c, a reasonable limit should be fixed for the proportion of the cheap food to be added Out of 23 samples of butter and margarine 22 contained boric acid One sample of butter contained about 37 per cent of margarine, another of "cooking butter" contained 66 per cent of margarine, while a margarine sample contained 14 per cent more butter than the legal maximum of 10 per cent

Preston

Dr F A Sharpe points out that the great towns of Lancashire and Cheshire showed a marked increase in infant mortality as compared with 1924 Several had rates over 100, and Preston's rate of 131 was the highest of the 105 great towns of England and Wales In seeking for an explanation Dr Sharpe refers to the severe winter, the pollution of the atmosphere by smoke, especially by industrial plants, the three years of severe depression in the textile and engineering trades, and, lastly, the bad housing The decline in the mortality, resumed during the post-war trade boom, has been stopped by "the four lean years" Dr Sharpe refers to the large body of opinion in favour of the thesis that the decline in the tuberculosis mortality is more dependent upon a generous supply of food than upon any other factor, and he thinks we must anticipate a continued slight rise until the trade depression lifts "The heavy loss of life of women at childbirth deserves careful attention The tendency is in an upward direction Over 100 women have died in childbirth in the last ten years" Only 73 expectant mothers attended the antenatal centres, but this small number is partly due to the opening of an antenatal clinic at the Preston Royal Infirmary During the year a concerted effort was made to organise a nursing service available for all classes of society Hitherto the only nursing available has been a nursing sisterhood for Roman Catholics, a Poor-law nurse, and a nurse maintained by the parish church nursing association As the result of a public meeting and appeals the Preston and District Nursing Association has been started The milk samples examined for tubercle numbered 235, and of these 14 were positive As a result 13 cows with tuberculosis of the udder were removed from the milking herds and slaughtered under supervision During the inspection of cattle at the abattoir 79 udders were found to be affected with tuberculosis The majority of these animals were old cows and came from districts outside the area from which milk is drawn for the borough During May and June an outbreak of scarlet fever comprising some 10 cases, was traced to infected milk "Notwithstanding the immense effort made by the corporation and by private enterprise to supply the deficiency in houses, there is still a very great need," and it has not been possible to proceed with the closure and demolition of insanitary buildings. Preston has a practically stationary population, and the 2075 houses erected since 1911 were more than enough for the slight natural increase of the population On Jan 1st, 1926, there were 2000 unsatisfied applicants for new houses

Grimsby

Dr B C Stevens reports that the V D clinic has been removed from cramped premises in the general hospital to a house acquired by the corporation, and is doing increasingly good work. A new hospital of 24 beds for advanced cases of tuberculosis is nearly ready There is at present provision for early cases in males, but none for females For surgical tuberculosis in children four beds in another county are available, but, says Dr Stevens, "eight of our own would be better" There are, at present, four health visitors, one tuberculosis nurse, and three school nurses In order to cope with the work adequately, and to avoid overlapping and the visitation in the same house or street by three persons instead of one, Dr Stevens suggests there should be eight health nurses doing all the necessary visiting, each for her own small district The scarcity of institution beds for cases of mental deficiency creates a difficult position. The local authority has made good progress with the building of houses, but the overcrowding is not reduced "Why?" asks Dr Stevens, "Because no houses are available at a rental of 10*s* or 12*s* a week suitable for the casual labourer or the poor" The high maternal mortality emphasises the need for a maternity home Including two deaths following upon illegal operations and one due to valvular heart disease during the puerperium, the maternal mortality from childbirth was 8 3 The maternity and child welfare medical officer, Dr Janet Hepburn, conducts an antenatal clinic on one afternoon a week. The number of first attendances during 1925 was 160 (total births, 1792) Particulars were obtained about the feeding of 1167 babies At three months 61 per cent were breast fed and at six months 47 per cent

MENTAL HOSPITAL REPORTS

The *Glamorgan County Mental Hospital* at Bridgend had 1833 cases under treatment on Dec 31st, which means considerable overcrowding The medical superintendent calculates that only 35 per cent of the admissions can hope for recovery, although there have been fewer cases of general paralysis The recovery-rate was 30 per cent and the death-rate 10·4 per cent, 87 post-mortem examinations were held There were two deaths from dysentery and seven from severe diarrhœa, which emphasises the need of a properly equipped laboratory, 93 patients are allowed parole and 55 were let out on trial, 12 with money allowances A cinema and wireless have been installed There is a consulting surgeon, but no dentist; 105 nurses hold their certificate and 50 more have passed the preliminary examination Plans are ready for a new admission block, which will be of great value in segregating the patients and reducing congestion The report includes notes from the three chaplains

The *Essex and Colchester Mental Hospitals* are at Brentwood and Severalls At *Brentwood* there were 1661 patients on Dec 31st The death-rate was 8 7 per cent and 112 post-mortem examinations were made Only 4 per cent of the deaths were due to pulmonary tuberculosis, which is now but little in evidence There was one case of dysentery. A very large proportion of the admissions were general paralytics, and for these malarial treatment is to be tried In the admission wards a clinical and examination room has been provided, but there are still no facilities for hydrotherapy The dentists attend twice weekly Fifty-two patients are allowed parole and there are open wards On the female side there is a weaving and handicraft room which occupies over 40 women An operating theatre, a general bathroom, new verandahs, and hot water installation have been completed Sixty-six nurses hold their certificate There are a number of imbecile boys in the hospital, and these now have two small rooms to themselves At *Severalls* there were 1669 patients The low death-rate of 5 5 per cent was a record for the hospital, and there has been no dysentery for two years Post-mortem examinations were held in 85 per cent of the deaths General paralysis is being treated by malaria; 122 patients were allowed out on trial, 49 having money allowances, while over 200 patients have parole within the estate, and three beyond The poultry farm is developing satisfactorily There is a small weaving-room, but more space is required for this industry The pathological laboratory is being enlarged, and the work done therein includes routine investigations of blood and cerebro-spinal fluid, the exploration of new tests for general paralysis, and routine examination for typhoid carriers, which has resulted in the discovery of six Ninety-six nurses now hold their certificate, and the supply of suitable candidates is greater than it was

The *City of Leicester Mental Hospital* at West Humberstone had 898 inmates on March 31st. The death-rate was 9 1 per cent. and the recovery-rate 41 1 per cent The cause of death was verified in 75 3 per cent of the cases The visiting commissioners remark that "the general atmosphere of the hospital was one of happiness and goodwill", 77 per cent of the patients are usefully employed and the medical superintendent urges the appointment of an occupation officer, remarking very rightly that the equipment of a mental nurse should include a knowledge of how to make useful occupation for her cases 47 per cent of the male and 36 per cent. of the female patients are on parole, and leave of absence has been granted 1395 times during the year A magazine, entirely produced by patients, has been widely circulated The pathologist submits his first report this year and records a small outbreak of dysentery, after which two carriers were discovered The question of carriers is being investigated An outbreak of ringworm drew attention to the possibility of this disease being more common in mental hospitals than is realised Malarial treatment was given to seven cases of general paralysis and to three of neurosyphilis Only one case showed improvement The dental surgeon reports that he has seen over 300 patients, and that all new admissions have also been examined While patients are under his care they undergo at the same time a course of oral hygiene in the wards, a most important adjunct to dental work He states that he is now seeing infinitely cleaner mouths than before Thirty-six nurses are certificated and three have the M.P A diploma.

The *Monmouthshire Mental Hospital* at Abergavenny houses 1167 patients and has 37 vacancies The death-rate was 6 4 per cent, and the cause was verified post mortem in 77 per cent of these There was an influenza epidemic and one case of dysentery, but otherwise the health of the patients was good The recovery-rate was 26 9 per cent, but many of the admissions were feeble or infirm and there was a high proportion of general paralytics All the sewing work of the hospital is done in the wards, and boots are both repaired and made The detached houses and two wards are administered on the open door system, and parole is allowed to over 100 patients within the grounds and 31 outside Shopping parties visit the town weekly A dentist attends weekly, and the appointment of a visiting surgeon is recommended by the commissioners During the year 11 nurses obtained their final certificate The report includes notes from the three chaplains

The *James Murray's Royal Asylum* at Perth had 163 patients on its register on March 31st, having had the largest number of admissions during the year on record, amounting to 55 5 per cent of the average inhabitants Just under 60 per cent were voluntary boarders and the authorities have found no difficulty in persuading these people to stay as long as required A few certified patients are allowed out on probation. The report includes no statistical tables The medical superintendent points out that the bodily health of patients admitted is generally poor, and discusses the relationship of pyorrhœa to mental disorder In some cases eradication of deeply-placed septic foci led to rapid improvement, but in others the results of drastic dental treatment were disappointing The death-rate was 9 3 per cent and post-mortem examinations were made in 10 out of the 14 fatal cases There were four cases of German measles, but no more serious epidemic As is the custom here, every available nurses at for the certificate examination of the Nursing Association.

The *West Sussex County Mental Hospital* at Chichester has 759 patients, and although not immediately pressed for accommodation, has approached two boards of guardians to see if they will receive quiet aged patients in their infirmaries The death-rate was 4 7 per cent and post-mortems were held in 78 per cent of cases A number of relieved patients have been sent out on trial, eight of them with money allowances Parole has been granted to 60 patients, and 14 per cent of the women wear their own clothes There was an epidemic of influenza, but otherwise the health has been good Individual attention is given in the kitchen to recovering patients who show any aptitude for cooking The excellent X ray apparatus is at present housed in a temporary hut 70 per cent of the male and 50 per cent of the female nurses are certificated or registered

The *Croydon Mental Hospital* at Warlingham had 713 residents on March 31st, and the recovery-rate for the year reached 52 38 per cent, 19 per cent higher than the average figure for county hospitals Accommodation has been taxed to the utmost The death-rate was 6 45 per cent The general health was good, there was only one case of dysentery The hospital has electrotherapeutic and X ray plant, and a new bacteriological laboratory is being fitted up A dentist attends weekly Malarial treatment has proved satisfactory for general paralysis, 50 per cent of the cases being discharged and continuing well A large proportion of the patients are usefully employed in various domestic offices and in mat-making The numbers out on trial are, however, still not great Twelve nurses have the M P A certificate and 13 more have passed the preliminary The three chaplains each supply a note to the report

The *Hertfordshire County Mental Hospital* at St Albans accommodates 904 cases and has an excess of beds, many of which are, however, occupied by out-county patients A three-valve wireless set, four pianos, and a billiard table have been added The report makes the important announcement that the committee have arranged to allocate an area of 130 acres of the estate for a mental deficiency institution The death-rate was 6 5 per cent, post-mortem examinations being held on 49 cases out of the 59 who died The recovery-rate was 40 8 per cent, an increase on the previous year. There was one case of diphtheria and one of enteric fever The male sick patients are successfully nursed by women The dentist treated 123 patients, and there were several major operations during the year One ward has been made "open" Thirty-seven nurses have their certificate, while 22 others have passed the preliminary examination

The *Brighton County Borough Mental Hospital* at Hayward's Heath had 828 cases in residence on Dec 31st There has been no dysentery since 1924 and no epidemic disease save one case of mumps Full parole has been given to 47 patients, without untoward result The recovery-rate was 57 3 per cent for males and 39 5 per cent for females A wireless set has been fixed and electricity is being installed. Forty three nurses hold their certificate and 24 more have passed the preliminary test The chaplain and dentist also present reports; the latter attended 435 patients Last year a dressmaker was appointed to supervise the making of the women's clothes and to make an attempt to get away from stereotyped patterns Unfortunately, there is no admission ward and new cases have to be treated amongst the chronics There is a possibility that an out-patient clinic may be started in Brighton; it is to be hoped that this important venture will mature successfully

The *Kingseat Mental Hospital*,' Aberdeen, had 628 patients at the end of the year, an increase of nine It is still in the unfortunate position of having to refuse voluntary patients because the parish council receive a small grant for certified cases The medical superintendent justifiably complains of this reactionary and obstructive policy There was a recovery-rate of 38 per cent and a death-rate of 6 8 per cent As there was continual diphtheria and scarlet fever in the district the patients and staff were tested and "positives" immunised, and since then there have been no cases of epidemic disease The hospital has long been overcrowded and mental defectives have been treated in association with other patients In addition to its prejudicial effect on the patients, this also makes the nursing more difficult and discourages the staff All will welcome the relief afforded by the new villas, which will soon be ready for use

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED AUGUST 28TH, 1926

Notifications —The following cases of infectious disease were notified during the week —Small-pox, 90 (last week 62); scarlet fever, 1036, diphtheria, 725, enteric fever, 59; pneumonia, 361, puerperal fever, 42, cerebro-spinal fever, 11, acute poliomyelitis, 40, acute polio-encephalitis, 2, encephalitis lethargica, 39, continued fever, 1, dysentery, 11, ophthalmia neonatorum 104 There were no cases of cholera or typhus fever notified during this week The case of bubonic plague at Liverpool will come into next week's return

Deaths —In the aggregate of great towns, including London, there were no deaths from small-pox, 2 (0) from enteric fever, 10 (0) from measles, 5 (2) from scarlet fever, 31 (6) from whooping-cough, 24 (6) from diphtheria, 124 (23) from diarrhœa and enteritis under 2 years of age, and 18 (4) from influenza The returns from diarrhœa and enteritis, although showing a rise of about 25 per cent. on the figures of the previous week, are not much more than one-half the figures of the corresponding week a year ago The figures in parentheses are those for London itself

---

A CASE OF BUBONIC PLAGUE IN LIVERPOOL.—In the case of a boy of 10, who became ill on August 27th and died in hospital on August 30th, the diagnosis of plague has been confirmed by the bacteriologist of the Ministry of Health The boy's father, a dock employee, is himself in hospital recovering from an illness the symptoms of which are suggestive that he, too, may have suffered from plague. The remaining members of the household are under supervision and steps to prevent the spread of infection are being taken by the Liverpool Public Health Department

TREATMENT OF TUBERCULOUS INSURED PERSONS IN IRELAND —At the meeting of the National Association of Insurance Committees in Dublin last week a discussion was held on the treatment of tuberculous insured persons It has been the experience of many committees that the sanatorium fund is insufficient for the adequate treatment of all tuberculous insured persons On the other hand, the local authorities were unwilling to undertake the treatment of insured persons in excess of the number for whom payment could be made by the insurance committees A deputation from the Association recently waited on Dr E Stephenson, chief medical officer of the Department of Local Government and Public Health and stated that the insufficiency of the sanatorium benefit fund was largely due to non-compliance with the Insurance Acts, and suggested that the Government should meet its moral obligations to insured people who had complied with the Acts Dr Stephenson in reply, admitted the hardship for insured persons, but said that his Department was concerned to safeguard the ratepayers If the deputation submitted their views in the form of a memorandum he would submit it to the Minister

Correspondence.

"Audi alteram partem"

HELIOTHERAPY IN PULMONARY TUBERCULOSIS

To the Editor of The Lancet

Sir,—I was greatly interested to see the article by Dr J E Wood on this subject in your issue of August 21st There appears to be a dread of employing sunshine in pulmonary tuberculosis, in spite of its recognised value in other forms of the disease This fear would seem to be very largely hypothetical In January of this year Dr Rollier very kindly showed me a large number of cases in his wonderful clinics at Leysin I asked him particularly about the effect of sunshine in pulmonary tuberculosis He replied that he was a surgeon and not a physician, and did not deal with pulmonary cases except where so-called surgical and pulmonary tuberculosis coexisted In such cases he gave full sunshine treatment, with apparently excellent results I examined these cases and was very favourably impressed by them Disease that was presumed to be hilum tuberculosis was treated as a routine by heliotherapy, and the cases did exceedingly well Dr Rollier constantly pointed out that sunshine treatment failed to cure where there was a mixed infection without free drainage This condition, of course, obtains in many cases of phthisis But, after prolonged fresh air treatment the mixed infection is frequently overcome, and then sunshine treatment would be indicated I have often wondered whether it would be possible to drain a cavity exteriorly where the pleura is adherent, if one large cavity was keeping up the mixed infection, and then to give sunshine treatment Heliotherapy, it would seem, would be indicated after thoracoplasty, apicolysis, and other surgical procedures where the collapse of the diseased part has presumably minimised the mixed infection One hears much talk of severe reactions following exposure to sunshine. This, however, is the same with surgical tuberculosis If the diseased part is irradiated too soon, or too much, a devastating reaction may occur This is avoided by following Rollier's technique exactly So would it be, I imagine, with phthisis, if the diseased part were only gradually approached and finally exposed cautiously, watching carefully any reaction until it was safe to give prolonged exposures I earnestly hope that an extended trial will be made of heliotherapy in pulmonary tuberculosis

I am, Sir, yours faithfully,
F G Chandler, M D , F R C P

London, N W , August 30th, 1926

THE TECHNIQUE OF BLOOD TRANSFUSION

To the Editor of The Lancet

Sir,—Mr Keynes made a noteworthy improvement in the apparatus for transfusion of blood, but in using it I found certain disadvantages which it seemed impossible to obviate Mr Keynes without making trial of the modifications I have suggested criticises and condemns them The crucial point is whether or not the risk of contamination is merely academic I would maintain that for the purposes in view, involving repeated transfusions carried out in the ward or in the private house, this risk is not negligible The liability to clotting is largely dependent upon the modifications introduced to prevent contamination But even when using Keynes's method of collecting the blood, clotting does take place occasionally both in the tube and in the needle It is not so much a question of the rate of flow, as Mr Keynes suggests, as of its intermittency, and this is beyond the control of the operator I must confess that it is astonishing to me that Mr Keynes in the course of his eight years' experience has not met with this difficulty It would be interesting to have the experience of others His assertion that clotting in the needle cannot be prevented by using the apparatus in question is only worth consideration if it is founded on experience

As regards the toxicity of the dose of citrate that I mentioned, I can only say that my results bear out the opinion of Lewisohn, as quoted by Mr Keynes in his monograph on Blood Transfusion, that 5 g of sodium citrate is innocuous to man But I am surprised that it did not occur to Mr Keynes that in using my method he can use whatever concentration of citrate he likes He himself has pointed out that the tonicity of the solution is a matter of little importance Incidentally, it is another advantage of my method that the amount of citrate used can be accurately regulated to the amount of blood actually withdrawn The elaborateness of the apparatus is more apparent than real I have myself collected 400 c cm of blood without assistance

I am, Sir, yours faithfully,
London Hospital, Sept 6th, 1926 Paul C Gibson

To the Editor of The Lancet

Sir,—It is obviously desirable that the technique of so important a therapeutic measure as blood transfusion should be made as perfect and fool-proof as possible Dr Gibson attempts to improve the citrate method introduced by Mr Geoffrey Keynes His only objections to this method are first, that it does not eliminate the clotting difficulty, and, secondly, that the open method of collection is used which carries with it the risk of contaminating the blood

In my experience, when one has mastered the technique of the Keynes method, the clotting difficulty does not exist, while to avoid contaminating the blood during collection an elaborate complication such as that described is unnecessary A plug of cotton-wool is effective, or, if suction is used, as I believe it may be with advantage, a rubber stopper fitted with an inlet tube prevents infective material falling into the flask

I would suggest that the Keynes method, except for minor unessential modifications, as a citrate method, is incapable of improvement While acknowledging much valuable practical advice in Dr Gibson's paper, I feel it regrettable that he has not applied his obvious ingenuity to effect some improvement in the methods which badly need it—namely, those for administering whole blood without addition of anti-coagulants

Blood transfusion in the treatment of medical diseases may not have achieved the brilliant results commonly obtained in surgical cases, but to conclude that "it is at any rate desirable that the remedy should be given a careful and exhaustive trial before it is decided finally to abandon it" is a singularly pessimistic view, suggesting that Dr Gibson so far has not found his results commensurate with the technical labour expended

I am, Sir, yours faithfully,
Kenneth Stone

AN UNUSUAL DISABILITY

To the Editor of The Lancet

Sir,—I recently examined a man with a complete ankylosis of the left hip and in which the left knee was involved His chief complaint was that, although he could fully undress himself when going to bed at night, he required help to dress himself in the morning At first sight this did not appear quite clear and it required an actual demonstration to prove it He was unable to reach his left foot with either hand He wore shoes and by using his right foot was able to remove the left shoe, and he was able to remove the left sock by means of his right toes He may in time to able to educate the toes of the right foot to complete his morning toilet unaided, but this at present appears an impossibility —I am, Sir, yours faithfully,
J J Scanlan

Old Broad street, London, E.C , Sept 6th, 1926

THE CARDIAC CIRCULATION AND DISEASE

To the Editor of The Lancet

Sir,—In his valuable paper in your last issue Dr Geoffrey Bourne states that an agency that could reduce the frequency of the heart-beat like digitalis would be of great therapeutic value May I remind your readers that, as has been long ago and repeatedly pointed out by good observers, we have such an agency in *cold* ? In acute disease the heart is singularly responsive to local applications of cold, and the vicious circle of threatening heart failure may often be broken thereby In chronic conditions of rapid heart from myocardial weakness, cooling (but not "hot") baths of various kinds may similarly be relied upon to increase the force and diminish the frequency of the pulse

The relation between the diastole and the nutrition of the heart is an interesting one, and Dr Bourne's view agrees with the observation that many persons with feeble but slow hearts are long lived It may be noted that cold applied to the precordium during hot baths and applications often prevents acceleration of the heart This method, known at Pistyan as "heart-cooling," enables thermal treatment to be used in many cases of debility, "rheumatic" and other

PASTEURISATION OF MILK

To the Editor of The Lancet

Sir,—It is a wholesome sign of the times when someone like Mr. McLachlan does not fear to take his stand against the sophistication or doctoring of natural food Many years ago I had a hard fight in an English residential town—Cheltenham—to kill the trade of selling sterilised milk; now, I have not the least doubt but that 90 per cent of a section of the population of that town alone would have been rickety had this section's mothers not had the good sense to be impressed by my simple reasoning "What nourishment is the little one having ?"—the little one being the picture of pre-rachitic hæmic impoverishment "Cow's milk," was the reply "Cow's milk, boiled or sterilised" "Why?" "I thought it killed the germs" "Is a mother's milk boiled or sterilised ?" That settled the doom of the laboratory worker's advice The true test of a food was, and is, the effect on the nutrition and development and strength of the consumer, and the wise man was the one who foresaw what would happen to the consumer in 10 or 12 years My experience is that the laboratory worker has never done this Pasteurised milk has, and will have, the same deplorable results as boiled or sterilised milk, because, and this is the all-important point, *it is cooked* Anyone can perform the following experiment Place an egg in water for 30 minutes at the temperature of 145° F and the result is *a cooked egg*, and do not pasteurisers frequently proudly say that they hold the milk at 150°, *or thereabouts*, for half an hour ? The nutritional, developmental, and sthenic value of milk is destroyed by pasteurising, and it does not need much prevision to know that rickets and its congeners are in the future to wreck or to ruin the health of the young

No one is much to blame, and least of all the parents, but anyone who has studiously observed, over a series of years, the lamentable effect of feeding anyone on sophisticated or doctored milk can only be doing a public duty by persisting in pointing out the destructive effects on the growing body organism —deformity and maldevelopment, asthenia, predisposition to disease, and inability to withstand any morbid process In effect, the same condition results to a food from pasteurising as from the use of a preservative such as boric acid; there is devitalising of organismal life—i e, of bacterial life—not destruction, and there is devitalising of the cellular life of the food itself Now, surely, mothers, educated doctors—i e, those who have jettisoned much of the impedimenta of their schooling—and laboratory workers all know the baneful results of boric acid and other similar preservatives on foodstuffs, whether for the child or the adult

I am, Sir, yours faithfully,

R Cunningham Affleck

Edinburgh, August 27th, 1926

NOMENCLATURE OF ABNORMAL UTERINE HÆMORRHAGE

To the Editor of The Lancet

Sir,—I am interested in Prof Blair Bell's criticisms in your last issue of the nomenclature suggested and approved at the Nottingham meeting of the B M A. for the varieties of abnormal uterine hæmorrhage, and I welcome this opportunity of clearing up any doubts that may still exist in his mind and in those of others I am indeed sorry that illness prevented him from being present at the discussion in question which, if it has done nothing else, has served to focus attention once more upon the urgent necessity for standardising a nomenclature in connexion with this subject I do not claim on this occasion to have put forward anything new in the matter of terminology What I did attempt to "propound," if this word must be used, was a pathological basis to substantiate terms which are already in use Mere names to cover symptoms do not appear to have much value unless they are backed up by pathological facts

The nomenclature I used in my paper at Nottingham is practically the same as that employed by me in my article on Uterine Hæmorrhage in the "Practitioner's Encyclopædia of Obstetrics and Gynæcology" (Fairbairn), published in 1921 Here Prof Bell will find that full credit is accorded to him as regards the word "epimenorrhœa" "Menostaxis" was a term introduced by me in 1921 to designate a prolonged "period" and which has, as a pathological basis, a patchy necrosis of the endometrium It is in other words, an incomplete menstrual abortion, and is a distinct entity "Menorrhagia," in the sense in which I employ and teach the term, is a short, sharp hæmorrhage due to atonicity of the uterus, probably with a neuro-muscular basis It is analogous to post-partum hæmorrhage Both "menorrhagia" and "metrostaxis" are terms that have long been in use, and neither Prof Bell nor I lay claim to any originality in the matter Prof Bell complains that in the classification accepted at Nottingham no reference is made to his term "epimenorrhagia" I did not include it because candidly I could not see the necessity for it As I understand the word it means too frequent and too excessive periods It has no definite pathological basis apart from what is included under the other names, and to my mind is mere hair-splitting One of the great difficulties in investigating uterine hæmorrhage from a clinical standpoint is that not only two but sometimes three of the standardised varieties may and do occur together If each one of these numerous possible combinations is to be honoured with the dignity of a name such as "epimenorrhagia" an algebraical and pathological problem is set which I am only too pleased to leave to Prof Bell to elucidate

The Nottingham classification of uterine hæmorrhage is at least based upon pathology in addition to symptomatology, and it has the merit of fact in addition to theory From a practical standpoint therefore, the matter amounts to this—the old terms of "menorrhagia" and "metrostaxis" are retained with the limitations noted in my opening paper, the comparatively new terms "epimenorrhœa" and "menostaxis" are introduced to designate specific pathological types of bleeding and the name "epimenorrhagia" is dropped as being redundant In this "new" terminology what is good of the old has been retained and, of the new, I think the honours stand even

I am, Sir, yours faithfully

Beckwith Whitehouse.

Obituary.

J HOWARD MUMMERY, C B E D Sc PENN, F R C S ENG, L D S

We regret to announce the death at the age of 79 of Mr J Howard Mummery who had for many years been a recognised leader of the dental profession not only in this country but among pathologists in every scientific centre

Mummery was the son of a distinguished scientist and dentist, J R Mummery who was one of the first to investigate the incidence of dental caries among different races and whose work is still quoted as authoritative He was educated privately and received his medical training at University College Hospital where he early commenced work as a microscopist and started investigations in the difficult field of dental histology which he was pursuing within a few weeks of his death

J HOWARD MUMMERY

As a histologist Mummery's ability can have been equalled by few and rarely excelled The dental tissues present so many technical difficulties that the investigation of their minute structure calls for exceptional skill and patience In this work he was supreme, and his additions to our knowledge of the normal and morbid structure of the teeth have played a great part in creating a scientific conception of dental disease and its treatment Dental anatomy plays an important part in zoology, so that his labours were appreciated not only by dentists but by all biologists and anthropologists He was among the first to describe adequately the development of dentine, and his account, written as far back as 1892 is still generally accepted His best-known piece of research was that on the innervation of the highly sensitive dentine Since the dental pulp is richly supplied with nerve-fibres, it would seem natural to suppose that these eventually enter the tubes of the dentine For many years histologists sought to demonstrate this point but without success for the technical difficulties of preparing sections to show a hard tissue like dentine and a delicate tissue like the pulp in their anatomical relation without distortion were extremely great Mummery took up the problem and laboured at it long and unceasingly, and eventually after work, the magnitude of which only a few of his friends realised, he was able to demonstrate that the nerve-fibres passed into the dentinal tubes His results were published in the *Philosophical Transactions* of the Royal Society, and attracted widespread attention and some criticism, not all of which was either fair or pertinent On the whole, it may be said that histologists generally, and not only those engaged in dental research have accepted Mummery's conclusions

Among Mummery's other important contributions to dental pathology may be mentioned an inquiry into the various forms of inflammation of the pulp and the morbid anatomy of the odontomata, but indeed there are few branches of dental science to which he did not make additions of first-rate importance As a worker he was painstaking and exact and nothing but the best that he could do satisfied him Were he studying any point in dental histology he would cut scores of sections before he could come to any conclusions that he would publish or depend upon and would remorselessly scrap sections that many would have been proud to have prepared As a result his various papers possess high value, and his conclusions as to the structure of the dental tissues have been generally upheld by subsequent workers Nor was he merely a technician of great skill, he was a vigorous and clear thinker, with a wide knowledge of general anatomy and pathology which he brought to bear on the various dental problems that occupied his attention His unwillingness to publish anything until he was sure of his ground is exemplified by the fact that at the age of 72 he published his first and only book the "Microscopic Anatomy of the Teeth," and it was at once hailed as a highly original and important work A second edition was soon called for, and Mummery took the opportunity of adding a section on comparative anatomy which made this edition almost a fresh publication The book, like the manual of John and Charles Tomes, is already a classic in its own domain

Mummery retained his mental vigour unimpaired to the end and was engaged in active research up to within a few weeks ago It is not given to many men to add substantially to their fame after the age of 70, but Mummery did so, and in many respects the last decade of his life was the most fruitful A serious illness a year ago, from which he made a rather remarkable recovery, impaired his strength considerably, but his brain was as alert as ever, and though he tired more easily his hand lost none of its skill Within the last three months three papers of histological research, all of first-rate importance, were written by him and have been published A correspondent who worked with Mummery often during the last few years records it as an inspiring sight to watch this passionate devotion to knowledge, sometimes checked but never stopped by the diminution of the physical powers "Mummery in private life," he adds, "was a charming companion, humorous widely read, and with many artistic interests He was moreover, one of the kindest of men and loved nothing better than to place his great knowledge at the disposal of others Indeed, he was almost prodigal of his time in helping younger men Though few of his contemporaries survive, yet he kept on adding to his friends, for he was always prepared to receive new ideas, and up to the end retained an elasticity of outlook that was positively youthful"

Mummery received the C B E for his services during the war in connexion with the treatment of injuries of the jaws, the University of Pennsylvania conferred on him the D Sc in recognition of his general services to dental science, and the Royal College of Surgeons of England made him an honorary Fellow He was a member of the committee for the investigation of dental disease of the Medical Research Council and carried out useful researches for that body He was one of the few dentists whose reputation was international and his death is a loss to the medical profession which he served with such keenness and genius

SAMUEL ARTHUR POWELL O.B.E., M.D. BELF., M.CH. R.U.I., J.P., V.D.

LIEUT COLONEL IN CHARGE OF OFFICERS' HOSPITAL BOMBAY

THE death occurred on August 28th of Dr S A Powell after a short illness. "Dick" Powell was born at Bandon co Cork in 1864: was educated at Trinity College, Dublin, the Royal University of Ireland and Belfast. He qualified M B R U I in 1887 and M Ch the same year. A brilliant surgical future was expected of him but he was attracted away from Belfast to the more adventurous life offered by a civilian post in Assam. Here he became interested in field observation and did some valuable laboratory work on obscure problems of tropical disease before he again changed his work for that of a police surgeon in Calcutta. When the South African war broke out Powell became medical officer to Lumsden's Horse, being frequently mentioned in despatches, but after that war returned to India as police surgeon in Bombay. He gained considerable experience in toxicology and medico-legal matters and was appointed to the Professorship of Jurisprudence in Grant Medical College Bombay; some of his work is incorporated in chapters of Lyon's Medical Jurisprudence. As a lecturer he was lucid and incisive interesting Indian students because he understood their standpoint and appreciated their difficulties in acquiring knowledge given in a language not their own. He also acted as professor of biology: his lectures were chosen carefully and illustrated by native types of plants and animals not imported specimens from Europe. His Practical Biology for Indian Students has been through many editions and remains a model of how to apply general knowledge to local conditions. Dr. Powell was examiner to the Punjab and Allahabad Universities and held other academic posts. In the Senate of the Bombay University his local knowledge enabled him to reconcile conflicting opinions, and his incisive and ready wit outmanœuvred obstruction. When the Great War began Dr Powell was in Germany but was able to get back to Bombay and worked from 1915 to 1919 as Lieut-Colonel I D F commanding the Byculla Officers Hospital. The strain of the war affected his health and he was compelled to leave India. After a time he took up consulting work in tropical diseases in London contributing several papers to the Royal Society of Medicine and the Royal Society of Tropical Medicine. He acted as consulting physician on tropical diseases to the Ministry of Pensions.

Powell was above all a clubable man. He was popular with all classes and races in India and had many hobbies. In his early days in Assam he ran a training stable for a time and rode his own horses. His sympathetic understanding of the Indian people enabled him to clear away many misunderstandings and he had an intimate personal knowledge of the criminal classes that lent point and humour to his lectures on medical jurisprudence. Many of his old pupils in India will regret to learn of his death.

CECIL JOHN DAVENPORT F.R.C.S. ENG., L.R.C.P. LOND.

ON Sept 4th Mr C J Davenport died suddenly in Shanghai at the age of 63. Mr Davenport was born in Adelaide South Australia and came to England to study medicine at St Bartholomew's Hospital where he qualified M R C S, L R C P in 1887 taking the F R C S Eng in 1889. After holding resident posts at his teaching hospital he proceeded to China in 1889 under the auspices of the London Missionary Society and established a medical mission in Chungking. After some years of pioneer work there he was moved to Wuchang where he carried on the medical work till invalided home at the time of the Boxer rising. In 1905 he was appointed medical superintendent of the Chinese Hospital Shantung-road Shanghai—the post he held till his death. Originally a mission hospital but under the control of local committees in 1905 the hospital was in low straits from lack of qualified staff. Under Mr Davenport's superintendence it has risen to a high standard of efficiency, many thousands of poor Chinese being treated yearly in the wards and out-patient departments and many doctors and nurses being trained. Recently a sum of over £300,000 was left by the late Mr H Lester of Shanghai, for its development and endowment and though Mr Davenport's retirement had previously been planned to take effect next year, he was being pressed to remain in Shanghai and give his advice and help in the administration of the benefaction for the hospital and its proposed medical school. The extent of his administrative duties had forced him to give up much of his surgical work to his lasting regret. Mr Davenport's sudden death is a severe loss to the local community where his judgment and vision were widely appreciated. He had no wish for personal advancement or distinction but as a president of the China Medical Missionary Association and the recipient of a decoration from the Chinese Government he was shown some formal recognition in recent years. Mr Davenport's life was given up entirely to the forwarding of his work: his keenness upright character and kindliness endeared him to the many of all nationalities with whom he was brought into contact. The chaotic state of the China he loved and the events of the past few years were causes of much anxiety and grief to him but his efforts to improve the conditions of medical work in that country were maintained to the end. He married in 1890 Miss Miles who prior to the marriage was Sister Martha at St Bartholomew's Hospital and was one of the first fully trained British nurses to go to China. He had two daughters and a son Robert Cecil who is in practice as an ophthalmic surgeon in London.

CENTENARY OF COOMBE LYING-IN HOSPITAL DUBLIN

As already announced the Coombe Lying-in Hospital is celebrating its hundredth anniversary from Tuesday Sept 14th to Friday Sept 17th. The proceedings will open with a reception at the Royal College of Surgeons by the Governors of the Hospital on Tuesday at 8 15 P.M. On the following day the centenary congress will be opened by its President *Sir William Smyly* at the Royal College of Surgeons at 9 30 A.M. A paper on Obstetrical Teaching in Sweden, by Prof Essen Möller will be followed by a discussion in which Prof A Couvelaire of Paris Prof Munro Kerr Dr L Cassidy Prof Fletcher Shaw and Mr Comyns Berkeley are expected to take part. At 11 15 Prof J. P. Faure of Paris will show a film illustrating abdominal hysterectomy and the rest of the morning will be devoted to papers on the Unnecessary Induction of Labour, by Mr Eardley Holland and the Treatment of Climacteric Hæmorrhages by Prof Paul Werner, of Vienna. In the afternoon the Coombe Hospital will be on view and in the evening there will be a dinner at the College of Surgeons. On Wednesday the opening paper will be read by Prof Munro Kerr, on the Lower Uterine Segment Cæsarean Section Operation. Prof J B de Lee, of Chicago Prof Möller Mr Eardley Holland and Prof Werner will join in the discussion. The remaining subjects of papers to be read on Wednesday are Two Important Advances in the Practice of Obstetrics and Gynæcology (Prof A Donald) Three Obstetrical Principles (Prof de Lee) and Some Problems in Antenatal Diagnosis and Prognosis (Prof Louise McIlroy). In the afternoon there will be a polo match in Phœnix Park between Coombe Hospital and the All Ireland Polo Club and in the evening a special performance by the Abbey Theatre Company. On Friday the proceedings are to open with a paper on Eclampsia by Prof H Hinselmann of Altona; this will be discussed by Mr Eardley Holland Dr J Hendry Dr Hugh Davidson and Dr Gibbon FitzGibbon amongst others. Papers will be read by Dr R W Johnstone on the Early Diagnosis of Cancer by Prof Beckwith Whitehouse, one on the Cause of Menstrual Pain and by Prof F J Browne on Intranatal Infection in the Newly born. From 4-6 P.M. there will be a garden party in the Zoological Gardens. Anyone wishing to take part in the discussions or the various functions should write to the hon secretary Dr L Cassidy at 6 Kildare-street Dublin who will be pleased to send programmes and cards of invitation.

Obituary.

J HOWARD MUMMERY, C B E , D Sc Penn , F R C S Eng , L D S

We regret to announce the death at the age of 79 of Mr J Howard Mummery who had for many years been a recognised leader of the dental profession not only in this country but among pathologists in every scientific centre

Mummery was the son of a distinguished scientist and dentist J R Mummery, who was one of the first to investigate the incidence of dental caries among different races and whose work is still quoted as authoritative He was educated privately and received his medical training at University College Hospital where he early commenced work as a microscopist and started investigations in the difficult field of dental histology which he was pursuing within a few weeks of his death

J Howard Mummery

As a histologist Mummery's ability can have been equalled by few and rarely excelled The dental tissues present so many technical difficulties that the investigation of their minute structure calls for exceptional skill and patience In this work he was supreme, and his additions to our knowledge of the normal and morbid structure of the teeth have played a great part in creating a scientific conception of dental disease and its treatment Dental anatomy plays an important part in zoology, so that his labours were appreciated not only by dentists but by all biologists and anthropologists He was among the first to describe adequately the development of dentine, and his account, written as far back as 1892 is still generally accepted His best-known piece of research was that on the innervation of the highly sensitive dentine Since the dental pulp is richly supplied with nerve-fibres, it would seem natural to suppose that these eventually enter the tubes of the dentine For many years histologists sought to demonstrate this point but without success for the technical difficulties of preparing sections to show a hard tissue like dentine and a delicate tissue like the pulp in their anatomical relation without distortion were extremely great Mummery took up the problem and laboured at it long and unceasingly and eventually after work, the magnitude of which only a few of his friends realised, he was able to demonstrate that the nerve-fibres passed into the dentinal tubes His results were published in the *Philosophical Transactions* of the Royal Society, and attracted widespread attention and some criticism not all of which was either fair or pertinent On the whole, it may be said that histologists generally, and not only those engaged in dental research, have accepted Mummery's conclusions

Among Mummery's other important contributions to dental pathology may be mentioned an inquiry into the various forms of inflammation of the pulp and the morbid anatomy of the odontomata, but indeed there are few branches of dental science to which he did not make additions of first-rate importance As a worker he was painstaking and exact and nothing but the best that he could do satisfied him Were he studying any point in dental histology he would cut scores of sections before he could come to any conclusions that he would publish or depend upon and would remorselessly scrap sections that many would have been proud to have prepared As a result his various papers possess high value, and his conclusions as to the structure of the dental tissues have been generally upheld by subsequent workers Nor was he merely a technician of great skill, he was a vigorous and clear thinker, with a wide knowledge of general anatomy and pathology which he brought to bear on the various dental problems that occupied his attention His unwillingness to publish anything until he was sure of his ground is exemplified by the fact that at the age of 72 he published his first and only book, the "Microscopic Anatomy of the Teeth," and it was at once hailed as a highly original and important work A second edition was soon called for and Mummery took the opportunity of adding a section on comparative anatomy which made this edition almost a fresh publication The book, like the manual of John and Charles Tomes, is already a classic in its own domain

Cassidy, Prof Fletcher Shaw, and Mr Comyns Berkeley are expected to take part. At 11 15 Prof J P Faure, of Paris, will show a film illustrating abdominal hysterectomy, and the rest of the morning will be devoted to papers on the Unnecessary Induction of Labour, by Mr Eardley Holland, and the Treatment of Climacteric Hæmorrhages by Prof Paul Werner, of Vienna In the afternoon the Coombe Hospital will be on view, and in the evening there will be a dinner at the College of Surgeons On Wednesday the opening paper will be read by Prof Munro Kerr, on the Lower Uterine Segment Cæsarean Section Operation Prof J B de Lee, of Chicago, Prof Möller, Mr Eardley Holland and Prof Werner will join in the discussion The *remaining subjects of papers to be* read on Wednesday are Two Important Advances in the Practice of Obstetrics and Gynæcology (Prof A Donald), Three Obstetrical Principles (Prof de Lee), and Some Problems in Antenatal Diagnosis and Prognosis (Prof Louise McIlroy) In the afternoon there will be a polo match in Phœnix Park between Coombe Hospital and the All Ireland Polo Club *and in the evening a special* performance by the Abbey Theatre Company On Friday the proceedings are to open with a paper on Eclampsia by Prof H Hinselmann of Altona, this will be discussed by Mr Eardley Holland Dr T Hendry Dr Hugh Davidson and Dr Gibbon FitzGibbon amongst others Papers will be read by Dr R W Johnstone on the Early Diagnosis of Cancer by Prof Beckwith Whitehouse *one on the Cause* of Menstrual Pain and by Prof F J Browne on Intranatal Infection in the Newly Born From 4–6 P M there will be a garden party in the Zoological Gardens Anyone wishing to take part in the discussions or the various functions should write to the hon secretary Dr L Cassidy at 6, Kildare street Dublin, who will be pleased to send programmes and cards of invitation

The Services.

ROYAL NAVAL MEDICAL SERVICE

The following appointments are notified —Surg Comdrs F G H R Black to *Victory*, for R N Hospl, Haslar, temp, supy, H H Babington, loan to R A N cancelled, G G Vickery to Canterbury (on transfer), J A Maxwell to *Pembroke* for R N Hospital, Great Yarmouth (temp), J Bourdas to *Furious* (on recommg), A G V French to *Malaya*, and to *Malaya* (on recommg), and H M Whelan to *Ganges* for R N Sick Quarters, Shotley

Surg Lt-Comdrs F G Hunt to Dartmouth on commg for voyage out and home, H Hurst to *Carysfort* and to *Carysfort* for voyage out and home, and J R Brennan to *Castor* and to *Castor* (on commg) for voyage out and home

Surg Lt S Morrow to *Furious* (on recommg)

Surg Lt R W Higgins, M V, to *Pembroke* for R M Infirmary, Chatham

Surg Lt (D) T E Brevetor to *Pembroke* for R N Barracks, Whatham

Surg Comdr M W Mason placed on Ret List at own request.

Surg Capt W L Martin to be Surg Rear-Admiral

Surg Lt-Comdr H Wilks to be Surg Comdr

Mr J K G Way, as Surg Lt, for short service, and appointed to R N Hospital, Haslar, for course

ROYAL NAVAL VOLUNTEER RESERVE

Surg Lt W Caithness to *Victory*, for R N Barracks, for 14 days' training

Surg Sub-Lt E I Puddy to be Surg Lieut

ROYAL ARMY MEDICAL CORPS

Maj M D Ahern to be Lt-Col., and remains secd, vice Lt.-Col R T Brown to ret pay

Maj and Bt Lt-Col C H Turner to be Lt-Col, vice Lt-Col M D Ahern (secd)

The undermentioned Capts to be Majs A E S Pringle-Pattison (Prov), with precedence next below H D F Brand, R H Alexander, R W Galloway, W Frier, F S Gillespie, R R G Atkins (Prov), W E Tyndall, G A Bridge

Capt (Prov Maj) G R Grant is restd to the estabt

Capt J McP MacKinnon is restd to the estabt

Temp Lt. C F McLean relinquishes his commn and retains his rank

J F Wilde to be temp Lt

TERRITORIAL ARMY

The King has approved of the following appointment — To be Honorary Surgeon to His Majesty Col Frederic H Westmacott, C B E, T D, F R C S, Assistant Director of Medical Services, 42nd (East Lancs) Division, in succession to Col E C Montgomery-Smith, C M G, D S O, T D, M D (Retd)

Maj (Prov) J A Stenhouse is confirmed in his rank

R McD Cairns, late R N V R, to be Lt

D S Middleton to be Lt

General List.—Qrmr and Capt D T Dixon retires on account of ill-health and retains his rank

ROYAL AIR FORCE

Group Capt A W Iredell to Headquarters, Inland Area, Stanmore, for duty as Principal Medical Officer

Flying Officers W W Coffey and J Hutchieson to Research Laboratory and Medical Officers' School of Instruction on appointment to Short Service Commissions

Flight Lt (Dental) H J Procter to No 5 Flying Training School, Sealand

Medical Quartermaster and Flying Officer C B Willsher is placed on the retired list on account of ill-health

INDIAN MEDICAL SERVICE

The King has approved the grading of the undermentioned officer with seniority as shown below in supersession of all previous notifications Capt (Prov) W Aitchison (June 20th, 1924)

Temp Lieuts to be temp Capts Dina Nath Ahluwalia, Bhann Datta Sharma Manmohan Nath Khanna

Surg Lt-Comdr S R Johnston, R N has been awarded Sir Gilbert Blane's Gold Medal, he having obtained the highest aggregate marks at the examinations held in 1926 for promotion to the rank of Surgeon Commander

Medical News.

Progress of the London Hospitals —The annual reports of several more of the London hospitals have just been issued

Royal Free —For seven months of last year 54 of the 218 beds were not available owing to alterations in the wards, but 2504 in-patients were treated at an average total cost of £9 16*s* 9*d* each There were more than 32,000 casualty cases Six small rooms for the use of private patients of limited means were opened and have been in constant use Also, two small wards for venereal, obstetric, and septic obstetric cases have been opened, together with a maternity clinic in Essex-road, Islington Lord Riddell lent 50 35 mg of radium The ordinary expenditure exceeded the ordinary income by £17,610

Brompton Hospital for Consumption —Last year 2535 in-patients were treated at a cost of £23 2*s* 1*d* each, and there were 4088 new out-patients Of the 476 beds available 449 were constantly occupied The hospital at Brompton cost over £60,000 and the Frimley Sanatorium over £20,000 to maintain A new wing of the hospital, with X ray rooms, is being provided at a cost of £25,000 (which has not yet been obtained) as a memorial of the late Lord Chevlesmore who was chairman for 21 years

St Mary's, Paddington —There were 4143 in patients, and the average cost per occupied bed was £163, as compared with the average of £184 of the hospitals which come within the purview of King Edward's Fund The annual subscriptions were the largest since 1911, but were still "almost absurdly low"

Seamen's Hospital —The 105th annual report of the Seamen's Hospital Society states that since the foundation of the Society 1,100,000 persons have been treated at the parent hospital at Greenwich, about one-fifth of whom were in-patients There were last year 3168 in-patients at the "Dreadnought" Hospital at Greenwich who cost a fraction under £11 each The Society possesses three other hospitals, including the Hospital for Tropical Diseases in Endsleigh-gardens, a sanatorium, a convalescent home and a dispensary, with a total of 542 beds The income last year exceeded expenditure by more than £9000

Health of Belfast —Dr H W Bailie's report for the year 1925 records the number of births registered in the city as 10,234, equivalent to a birth-rate of 23 4 per 1000 This is a decrease of 0 5 per 1000 compared with the previous year In the preceding ten years, 1915–24, the average annual birth-rate was 25 1 The number of deaths registered was 6131, equivalent to a death-rate of 14 per 1000, a decrease of 0 3 per 1000 compared with the previous year The average number of deaths for the ten years 1915–24 was 6829, being an average death-rate of 16 7 The number of deaths under 1 year of age was 1069, being 17 4 of the total deaths registered This represents a decrease of 3 per 1000 compared with the preceding year 1738, or 28 35 per cent., of the total deaths registered were caused by chest diseases, 575 being due to phthisis 517 to pneumonia, and 646 to other diseases of the respiratory system. Zymotic diseases accounted for 574 deaths, or 9 36 per cent of the total deaths registered 203 of these deaths were caused by diarrhœa, 99 by whooping-cough, 167 by measles, 49 by scarlet fever, 38 by diphtheria, and 18 by typhoid fever The death-rate from phthisis was 1 3 per 1000 of the population, from pneumonia 1 2, and from other diseases of the respiratory system 1 5, showing a decrease of 0 1 from phthisis, of 0 2 from pneumonia, and of 0 1 from other diseases of the respiratory system The death-rate from zymotic diseases was 1 3, an increase of 0 3 compared with the preceding year This increase was due to diarrhœa, measles, and typhoid fever The deaths from typhoid fever numbered 18, compared with 3 in the preceding year, an outbreak of the disease being due to infected milk sent into the city from a dairy situated outside the city No case of typhus fever or of small-pox occurred during the year The case mortality of scarlet fever was 3 per cent and of diphtheria 10 3 per cent There were 8 cases of encephalitis lethargica, of which 7 proved fatal The deaths from this disease in the previous year numbered 30 No case of cerebro-spinal meningitis or of poliomyelitis occurred during the year 299 samples of fresh milk were examined for tuberculosis, and 17 of these (5 7 per cent) were found to be infected In such cases steps are at once taken to prohibit the sale of milk from the infected farm until the dairy herd has been examined by the veterinary inspector of the district and the source of infection has been traced

INDUSTRIAL WELFARE SOCIETY—At the seventh annual lecture conference which opens to-day (Friday) at Balliol College, Oxford, and continues until Wednesday, Sept 15th, lectures will be given by Mr H A Mahony on Dental Service in Industry, and by Dr Innes H Pearse on the Future of Preventive Medicine in Industry, when Dr M L Dobbie Bateman will preside Mr Ralph C Hazell will give Some Experiences and Results of Welfare Work.

ROYAL ALBERT EDWARD INFIRMARY, WIGAN—The report for the year ending March 31st 1926, reports that the number of beds is not nearly sufficient to meet the demands of the large area served by the institution, the waiting-list numbers 150, of whom 80 are women The 3058 in patients who were treated to a conclusion were an increase of a patient a day over the previous year Of the total expenditure of £42,000, £1650 was derived from employees' contributions

FRENCH HEALTH RESORTS—For many years Mme Juppe-Blaise had charge at the Office Français du Tourisme of a bureau, conducted in the interests of medical men desiring information concerning the French spas Mme Juppé-Blaise is now opening an office of similar scope in premises adjacent to the British Medical Association headquarters, and informs us that for the present inquiries about hotels, prices, and travelling arrangements can be directed to her, care of the Financial Secretary, B M A

ALL RUSSIAN OPHTHALMOLOGICAL CONGRESS—The main items in the programme of this Congress, which will be held in Moscow from Sept 27th to 30th, are 1 Organisation of Medical Help in Eye Diseases Measures of Fighting and Preventing Blindness 2 Trachoma and its Prevention 3 Chronic Eye Diseases Methods of Diagnosis and Scientific Investigations 4 Individual Scientific Communications Further information may be obtained from Dr V N Polovtsev at the offices of the Red Cross Society of Russia, 150, Southampton-row, London, W C 1

MATERNAL MORTALITY AND MORBIDITY IN AMERICA—A national programme for the prevention of maternal mortality and morbidity throughout the United States is outlined by the Children's Bureau of the U S Department of Labour in a report on maternal mortality made public on August 30th The report is the work of Dr Robert Morse Woodbury, formerly director of statistical research for the Children's Bureau Dr Woodbury estimated that the total annual number of maternal deaths in the United States is more than 20,000 Comparison of the United States rates of maternal mortality with those of other countries shows that the United States ranks among those having the highest rates, such as New Zealand and Chile Analysis of the causes of maternal deaths in that country shows that the most important single cause is puerperal septicæmia, puerperal albuminuria and convulsions are among other causes noted, also accidents of pregnancy and labour and hæmorrhage Colour and nationality are also important factors In the report the preventability of maternal mortality is considered in the light of the analysis of causes and causal factors It is held that almost all the mortality from puerperal septicæmia is preventable by the rigorous observance of asepsis For the prevention of the most important causes of maternal deaths the essential recommendations by the bureau are Effective supervision by a public health agency over hospitals and over the training and admittance to practice of physicians, midwives, and nurses, and the requirement that all cases must be reported It is considered that other puerperal causes of death may be prevented in a large proportion of cases by proper prenatal and natal care of the mother The problem of prevention is therefore summarised by the Children's Bureau report as that of ensuring to every mother skilled assistance before and during childbirth A preventive programme is suggested by the report, of which the main outlines are as follows (1) Regulation of the practice of obstetrics by requiring a licence to practise from both physicians and midwives by establishing minimum requirements for obtaining such a licence, and by defining and prescribing penalties for malpractice (2) Regulation of public and private hospitals and maternity homes through legal provisions governing the establishment of such institutions, which should be licensed and subject to inspection (3) Legislation for the control of venereal diseases, including the making of these diseases notifiable (4) Requiring that puerperal septicæmia be made notifiable, as is now the case in a number of States (5) Provision through Governmental or public sources of better facilities for training medical and nursing personnel and more adequate clinics hospitals and maternity homes (6) Subsidies in aid of State or local activities by Federal or State governments (7) Educational work directed toward informing mothers of the need of adequate maternity care

BRITISH INSTITUTE OF PHILOSOPHICAL STUDIES—An interesting programme of lectures has been arranged for the forthcoming session beginning Oct 4th In the Michaelmas term the Hon Bertrand Russell will give two courses of lectures (1) on the Problems of Philosophy, (2) on Mind and Matter. Dr T. W Mitchell will deliver ten lectures on Medical Psychology, Prof G Dawes Hicks will deliver ten lectures on the Development of Philosophy since Kant and Prof C W Valentine a course of 20 lectures on General Psychology In the Lent term Dr C Delisle Burns will lecture on the Philosophy of Social Life, and Prof J S Mackenzie on Social Values A full syllabus of lectures can be obtained on application to the Director of the Institute, 88, Kingsway, London, W C 2

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c

POST GRADUATE HOSTEL Imperial Hotel, Russell square, W C 1

MONDAY Sept 13th—9 P M, Sir William Hale-White, K B E F R C P, will open a discussion on The Days of Richard Bright

FRIDAY Sept 17th—9 P M, Mr E Muirhead Little, F R C S, will open a discussion on Amputation Stumps

All medical practitioners cordially invited

Appointments.

New Sussex Hospital for Women and Children, Brighton COOK, BESSIE E, M B, Ch B Lond, has been appointed Temporary Honorary Assistant Anæsthetist, and SYMONDS, V WINIFRED M R C S, L R C P, has been appointed House Surgeon for a term of six months

The Chief Inspector of Factories has appointed Dr R P GAMMIE to be Certifying Surgeon under the Factory and Workshop Acts for the Bishop's Stortford District of the County of Hertford Dr J P MURPHEY for the Pontesbury District of the County of Salop, Dr F A JUCKES for the Horsham District of the County of Sussex Dr MARY A E SOMERS for the Weston super Mare District of the County of Somerset Dr F C ALTON for the Hollingbourne District of the County of Kent, Dr R J E CHRISTIE for the Earsdon District of the County of Northumberland, and Dr N F GRAHAM for the Tibshelf District of the County of Derby

Vacancies.

For further information refer to the advertisement columns

Ayr County Hospital—H S At rate of £100
Brighton Royal Sussex County Hospital—H S £150
Bristol General Hospital—Sen Res M O £200

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Newhaven, in the County of Sussex, at Thame, in the County of Oxford, and at Measham, in the County of Leicester

The Home Secretary gives notice that in consequence of the resignation of Col Albert Herbert Tubby, C B , C M G one of the Medical Referees under the Workmen's Compensation Act for the District of Clerkenwell County Court (Circuit No 41), the appointment held by him is vacant Applications for the post should be addressed to the Private Secretary, Home Office, Whitehall, S W 1, and should reach him not later than Sept 30th, 1926

Births, Marriages, and Deaths.

BIRTHS

CALWELL —On Sept 1st at Holland Park avenue, W , the wife of W K Calwell, M D D P H , of a son

CRONIN —On Sept 1st at Westbourne grove, W , the wife of A J Cronin, M D Glasg , M R C P Lond , D P H , of a son

DODD —On Sept 1st, at The Red House Dartmouth grove, Blackheath S E 10, the wife of Dr Fredk H Dodd—a son

FOULKES —On Sept 3rd, at Exeter, the wife of R K Foulkes, M B , B S Lond , of a daughter

HINE —On Sept 6th at Rossmore, Harpenden, the wife of Montague Hine, F R C S of a daughter

HORDER —On Sept 6th, at Findelen, London road, Tunbridge Wells, the wife of Cecil A Horder, F R C S of a daughter

NICHOLSON —On Sept 7th, at a nursing home, Leeds, the wife of Dr James Nicholson Riffa House, Liversedge of a son

VINT —On Sept 2nd, at Oaklands, Langton Green Tunbridge Wells, the wife of Morley Dyson Vint, M A , M B , B Chir Cantab , of a son

MARRIAGES

ANDERSON—ALLEN —On Sept 1st, at St Mary's, Comber, Co Down, William Arthur Anderson, M A , M D to Phebe Elizabeth, only daughter of Mr and Mrs Allen, Unicurval, Comber, Co Down, N Ireland, and The Elms, Iffley Oxford

GROSS—KUTNER —On August 10th, Malcolm Gross, M B , B S Lond , D P H , of Wolverhampton and Clapham, S W , to Adelaide Kutner, of Hampstead

MOSELY—SPURR —On August 24th, at St Marylebone Register Office, Frederick Maurice Mosely, B A Cantab , M R C S L R C P , of London, to Stella Margaret, second daughter of Dr Frederick Spurr of London and Hove Sussex

SCOTT—HOPKIN —On Sept 2nd at Paddington, John A A P Scott, L R C P Lond M R C S Eng , of Tottenham, to Gladys M Hopkin, of Tottenham

WARE—HOPPER —On August 31st, quietly, at Wimbledon, Sydney Arthur Thomas Ware, M R C S Eng , L R C P Lond , of the Sudan Medical Service, to Doris Thorne Hopper, of Torquay

WALSH—LE CREN —On Sept 2nd, at the Parish Church, Elmstead Market Essex Harold Victor Walsh M B , B Ch B A O Belf , of Ipswich, to Jeannette de Lisle, daughter of the late F B Le Cren

WILSON—ALLEN —On August 28th at York, William Brockie Wilson, M C M B Ch B Glasg , to Mary Young Allen, daughter of Mr and Mrs W Y Mercer, late of Homeleigh, Gainsboro'

DEATHS

BOSTOCK —On Sept 4th at Horsham Edward Ingram Bostock, M R C S Eng , L S A J P in his 81th year

DAVENPORT —On Sept 4th suddenly, at Shanghai, Cecil John Davenport F R C S , Medical Superintendent of the Chinese Hospital, Shantung road Shanghai, China, aged 63

MUMMERY —On August 30th at Trevone Bay, North Cornwall, after a short illness John Howard Mummery, C B E , F R C S Eng , L D S of Albert Bridge road, S W , aged 79

TANNER —On Sept 6th, at Eastern Lodge, Kempsey, Worcestershire Richard Canning Tanner M R C S Eng , and L S A , 1861, within five days of his 87th birthday

TONKING —On Sept 4th at Trevu, Camborne, Cornwall John Herbert Tonking, M B Lond , M R C S Eng , L R C P Lond , aged 62 years

VAUGHAN —On August 26th, at Bridgwater, Lieut Colonel W F H Vaughan, M R C S Eng L R C P Lond , late R A M C , son of W Palmer Vaughan

N B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages and Deaths

Notes, Comments, and Abstracts.

NOTES ON THE VALUE OF SWISS SANATORIUM TREATMENT *

By Alex Sandison, M B , B C Camb , B Sc Lond

THE justification for these notes is the fact that it has been my lot to make two tours of Swiss sanatoria at Montana, Leysin, Davos, Arosa, and elsewhere in the past four years, and during that period I have also had special opportunities for gauging the effect of treatment in Switzerland on a large number of cases of tuberculosis I have thus been fortunate in having facilities on the one hand for obtaining detailed knowledge of typical sanatoria in Switzerland, and on the other for observing their clinical results on a scale not often available to tuberculosis workers in this country It is on the basis of this experience that I have formed the opinions I express

It is a common belief in lay and medical circles that the high altitude, clear air, and sunshine obtainable in Switzerland produce results in the treatment of tuberculosis which are superior to those obtainable in this country On my first visit in March, 1922, I endeavoured to consider the matter in a strictly impartial way, and on my return felt that there was, on the whole, a balance of evidence in favour of Switzerland, but that it was very difficult to determine whether or not any particular case fell within the class that might expect to obtain peculiar benefit Since then I have had opportunity to compare over a longer period the progress of cases treated in Switzerland with those who remained in this country Such comparison does not, so far as pulmonary cases are concerned, show clearly any general superiority of one form of treatment over the other, and in making it I am assuming that the treatment in this country is given in a modern sanatorium situated in a healthy locality, and that the treatment in Switzerland is that provided in a typical Swiss sanatorium at an altitude of 4000–6000 feet

As the result of my second tour in June, 1925, I am more confirmed in the opinion that Switzerland holds out peculiar advantages only to a limited number of cases, that its special value is largely psychological, and that, leaving aside for the moment surgical tuberculosis, the average case of pulmonary tuberculosis is likely *in the long run* to do as well under appropriate sanatorium *treatment in* this country as in Switzerland This conclusion will not be accepted by many Swiss tuberculosis specialists, nor by some in this country In going round Switzerland one is amused by the unanimity with which the value of altitude treatment is emphasised, whilst at the same time one is told that these beneficial effects are only fully obtainable in the locality and at the altitude of particular sanatoria One resort is said to be too windy, but it retorts that the other is too dusty One is too high or too liable to mist, another is alleged to be in a windy valley In truth all statements may be true, but the implication that climatic conditions are ideal where you happen to have an institution, and deleterious elsewhere, can hardly be accepted, and leads the impartial inquirer to the conclusion that they are all equally good or equally bad

To my mind the real truth was expressed by the physician of a well known Swiss sanatorium who said to me "Treatment in Switzerland is *un traitement de luxe* Give me a patient to whom time and money are no object, who can, if necessary, live abroad after his treatment, and who is not worried as to ways and means, and I can almost promise to cure him in the course of years Time is essential, ample funds are essential, for the treatment I give implies the highest standard of comfort and diet But if the patient has only limited time, if his financial resources are slight he will do better to undergo a more intensive treatment, which he can probably receive equally well in England, and be content with the attainment of relative quiescence of the disease rather than complete cure "

I am increasingly of opinion that this expresses the true value of Swiss sanatoria as curative agents The idea that Swiss treatment provides a short cut to cure is not correct, nor do I think it true that save for the definite, though often temporary, psychological stimulation usually apparent in the earlier stages of treatment there is any certainty that benefit of a permanent character will result which might not have been obtained elsewhere In saying this I do not forget certain cases which, for reasons not clearly apparent, have assuredly benefited permanently from Swiss treatment after failing to make progress under other conditions I know of no certain test however, by which such cases can be recognised beforehand Moreover almost every form of treatment for tuberculosis, orthodox or unorthodox, can show cases of this kind, and one is inclined to believe that the improvement is a matter of idiosyncrasy rather than of treatment. Certainly no special form of treatment can on such cases alone be considered of generally applicable value.

---

* Based on a paper read before the Tuberculosis Society

The following are, to my mind, the main advantages and disadvantages of treatment in Swiss sanatoria—i e , altitude treatment—for *pulmonary* tuberculosis as compared with ordinary English sanatorium treatment. I exclude cases obviously unsuitable for altitude—e g , on account of cardiac defects.

Advantages of Treatment in Swiss Sanatoria

(1) *Psychological*.—The complete change of scenery and surroundings undoubtedly produces for a time an increased sense of well-being which has a beneficial effect on the pathological condition, but is rarely sufficiently strong or lasting to effect a permanent benefit. With this benefit, due to climatic and scenic change, are often associated the effects of suggestion. The patient has become imbued with the belief that in Switzerland, and there alone, will he regain his health, and the realisation of his wish produces a mental satisfaction which is at least more helpful to his body than the mental unrest of a man who is denied his dearest wish. Again, however, the physical effects of this wish-realisation are not necessarily permanent and when progress is slow reaction sets in.

(2) *Physical*.—Statistics are so inconclusive that I am inclined to believe that my general impression based on a detailed acquaintance for some years with the progress of cases treated abroad is as likely to be correct as any mass of statistics. Be it said at once that many, perhaps most, cases do improve physically at Swiss sanatoria, and their disease tends towards quiescence or even arrest. But so do many and even most treated in good sanatoria at home, especially the early cases. Swiss sanatoria complain that they do not get the cases early enough. So do English sanatoria, the truth being that good sanatorium treatment anywhere will probably produce good results in any early case. Similarly, Swiss sanatoria say they do not have the cases long enough. Given unlimited time, however, English sanatoria are as likely to produce quiescence or arrest as Swiss.

There are, however, cases where English sanatorium treatment has failed to produce quiescence or arrest, the condition becoming one of stagnation in unstable equilibrium, and in certain cases of this type Swiss treatment does produce good results, giving apparently the stimulation required for further and continued progress. This does not apply to all such cases, and it is most difficult to estimate the likelihood of it doing so in any particular case. It is for this type that I think Switzerland does hold out special advantages. Tuberculosis, however, is such an uncertain disease and sudden improvement occurs in such unexpected conditions, that dogmatism is unwise.

(3) *General Climatic Effect*.—The pure and invigorating air of the Swiss mountains and the large amount of sunshine cannot fail to produce the psychological stimulation I have referred to. Further, the freedom from dust and smoke is an obvious advantage. Certainly a case of tuberculosis is likely to do better in a Swiss sanatorium than in an English town or in damp, foggy, unhealthy conditions anywhere. To regard an English manufacturing town, with its dust, fog and smoke, narrow streets and cramped houses as at all comparable with a Swiss mountain resort is obviously ridiculous, yet such is the comparison implied in many arguments on the climatic benefits of Switzerland. The equivalent of Swiss sanatoria is of course good English sanatoria in healthy country districts. On such a comparison the final results of treatment, in my experience, are very similar.

Disadvantages of Treatment in Swiss Sanatoria

(1) *Expense*.—(*a*) *Travelling expenses* are considerable, especially if the patient has to travel as a stretcher case. (*b*) *Nursing* is nominally included in the fixed daily charge, but nursing at a Swiss sanatorium is a very different thing from what the Englishman is accustomed to and expects. The ordinary Swiss sanatorium nurse has not the training of our nurses, and the proportion of nurses to patients is much smaller than with us. In short, for anything beyond quite simple nursing and domestic service there is little provision in the English sense, and a patient with, for example, a severe hæmoptysis or other condition requiring frequent skilled nursing has to engage a special nurse at considerable additional cost. Thus the expenses of treatment may speedily mount to a very high figure, especially when removal to a less expensive place of treatment is impossible or dangerous owing to distance and the acuteness of the disease. Certain sanatoria run by English doctors with English nurses on English lines must be excepted from these remarks on nursing. (*c*) *Medicines* are invariably charged extra. Swiss chemists are a close corporation with special privileges. It is, I understand, illegal for a doctor in a sanatorium to dispense any drugs other than what is necessary in emergencies. Thus the chemists have a strong monopoly and charge accordingly. (*d*) *General*. Swiss sanatoria are usually commercial concerns. So, of course, are English private sanatoria, but there are degrees of efficiency in the detection of items on which additional charges may be made, and in Switzerland these items, though individually small, may amount to a surprising total in the monthly bill. (*e*) *Kurtaxe*. This local tax may amount to 6*d* or 1*s* a day.

These sources of extra expense could be regarded with more equanimity if there were more certainty of special advantage in return. For the rich they are unimportant, but to the average tuberculous patient these extra charges often produce a financial anxiety which may go far to counteract what special benefits there are in Swiss treatment. Their extent, moreover, is not usually realised before the patient has embarked on the treatment and they often come as a serious shock.

(2) *Diet*.—Swiss sanatoria naturally diet their patients according to continental standards and customs. Breakfast is a ‘café complet,” lunch and dinner are rather heavy meals with a predominance of oily ingredients and made-up dishes with a wearisome reiteration of veal as the staple meat. This is a welcome change for most of us when we go abroad on holiday, but as a continued diet for an Englishman, and especially a sick one, it often becomes wearisome.

I was informed by one medical superintendent that his diet scale was worked out with the greatest accuracy as to the ‘calorie value’ necessary for high altitudes. That may be true enough, but calories are not everything, and food taken without appetite and even with repugnance does not get sufficiently digested to be fully assimilated. This diet question is one of special importance to the patients who have to be in bed and get no exercise. I came across several instances where the patient was justifiably weary of a diet which, though ample in amount, was foreign to his tastes and customs and not sufficiently modified according to the condition of his disease. These remarks do not apply with the same force to the English run sanatoria mentioned in (1) (*b*) above, where the diet is much more like that of English institutions.

(3) *Alcohol*.—Swiss sanatoria lay great stress on forbidding smoking to their patients, but permit considerable use of wines, beer, and even spirits. English sanatoria take the opposite view. The sale of alcoholic liquors is, moreover, a source of revenue to Swiss sanatoria. I was told by one medical superintendent that his committee had called attention to the diminishing receipts on this account. The medical superintendent had rightly retorted that he was glad they were less, but the incident shows a conflict of aim between the management and the medical superintendent of the sanatorium.

Further, there are no licensing restrictions abroad comparable to ours, and it is ridiculously easy for a patient to get what alcohol he likes and when he likes outside, and I fear it is at times too easily obtained within the sanatorium itself. Thus any patient who has a tendency to alcoholic indulgence is usually subjected to considerable temptation. English sanatoria have, of course, their own difficulties with the alcoholic, but in general it may be said that the opportunities for alcoholism are much less in England and the attitude one of more active discouragement.

(4) *Discipline*.—Englishmen do not take kindly to foreign control and the foreigner does not usually know how to handle the Englishman. Hence there are always possibilities of trouble, for there is not the same type or method of discipline in Swiss sanatoria, and the headstrong patient is more likely to run amok. The development of fashionable winter sports near Swiss sanatoria is an obvious potential source of disciplinary trouble.

(5) The *Pension System*.—Apart from sanatoria where there is a resident medical staff, there are numerous so-called sanatoria at Leysin, Davos, Arosa, &c., which are simply boarding houses catering more or less exclusively for tuberculous persons. These “pensions” vary greatly in quality of accommodation—some are almost of sanatorium standard, others cramped and unsatisfactory. The charges are on the whole high, but do not include any medical or nursing attendance, such being separately arranged for, usually with a local doctor who is more or less directly attached to the ‘pension.’ There is rarely any control of the patient, who is practically as free as if he were in his own home. These “pensions” cannot be regarded without careful inquiry as at all equivalent to sanatoria, and their prospectuses give but a very partial indication of their nature.

(6) *Declimatisation*.—By this I mean that prolonged treatment in Switzerland *declimatises* the patient for life and work in this country. Swiss doctors will advocate more or less continuous residence and treatment in Switzerland for two, three, or more years. The result is that the patient comes to believe that he must always fly to Switzerland to avoid the

English winter and, in fact, he does find it harder to keep well in England, although his general condition may have been much improved

For the average tuberculous patient it is an obvious advantage to receive his treatment in climatic conditions broadly similar to those in which he has eventually to return to work The less climatic difference there is between the place of treatment and cure and the place where work can be recommended the more lasting the cure will be *This is in* itself a general argument against prolonged Swiss treatment, for to become acclimatised *to altitude is to become de*climatised to English conditions and makes resumption of work so much *the harder and the more* precarious

Thus, whilst a single year or 18 months in Swiss altitudes need not produce any serious declimatisation, continuous treatment there beyond that period, or regular return throughout each winter for several years, makes it more and more impossible for the average quiescent type of case ever to resume steady work in this country Once again, Swiss treatment is suitable for the man of independent means who can live where he likes, when he likes, but has its dangers *for the average man who has to work for his* living

Surgical, *Non-Pulmonary Tuberculosis*

So far my remarks have had reference to the treatment of pulmonary tuberculosis The value of treatment in Switzerland for surgical tuberculosis requires separate consideration.

There is ample evidence to show the directly beneficial effects of altitude and sun treatment *on surgical tuberculosis* The climate of this country cannot provide light and sun *to the same extent. On the other hand,* the recent developments of artificial light treatment already demonstrate that curative results can be produced by artificial heliotherapy, and the work of Sir Henry Gauvain at Alton teaches us not to disparage unduly our own climate Perhaps the special advantages of Switzerland for surgical tuberculosis are already to a considerable extent capable of reproduction in a "light department" Such artificial heliotherapy is, indeed, often given as an addition to the natural light treatment in Swiss sanatoria, for the sun does not always shine there It is as yet too early to say how far the "Alpine sun" lamp can rival the Alpine sun itself, but it is equally too early to deny its potentialities

The psychological advantages of Switzerland, previously alluded to, hold good in surgical as in non-surgical tuberculosis, and so *for that matter do the general disadvantages* except that the average nursing provision for surgical cases is of a higher standard but often at an extra cost

The present position seems to me to be as follows (1) Swiss treatment has real and specific value for surgical tuberculosis (2) This specific value can apparently be also obtained from artificial light treatment in this country *(3)* If artificial light treatment is available, therefore, it should first be given a trial (4) If the artificial light treatment does *not show good results in a reasonable time* it is legitimate to consider that the case should go to Switzerland and to anticipate good *results there from natural light treatment*

So far I have been considering treatment at altitudes It is necessary for completeness to allude to.

Cases of Tuberculosis Requiring Sun but not Altitude

These cases are typically those with severe chronic bronchitis, asthma, and emphysema added to tuberculosis. To them an English winter is undoubtedly likely to bring recrudescence of active disease with a possibility of fatal result They *cannot* stand altitude treatment, but they do need warmth, sunlight, and freedom from damp and fog Thus, they *are not suitable for* Swiss sanatoria, which are almost invariably situated at considerable altitude, and they can best find the *conditions they require* on the French or Italian Riviera Institutional treatment may or may not be necessary, according *to the severity of the* condition

---

MEDICAL MISSIONARY WORK

In a little book entitled "A Woman Doctor on the Frontier" (C of E Zenana Missionary *Society, 1925, 1s 3d*), Dr Charlotte S Vines has given a series of sketches of medical work as it is carried on in the remote districts of India. Here blood feuds and highway robbery appear to be the chief interests of the people, who die but rarely in their beds The tales now told emphasise the difficulties under which operations can be performed without untoward *results* The same missionary society has published another book, "Flashlights on Chinese Life," which was prepared by the late Dr Mabel Pantin just before her death It contains some vivid little snapshots of Chinese life, its pathos and humour, tragedy, and courage The book is illustrated by a number of photographs and some sketches, and will be welcomed by those who are interested in the life of Eastern peoples and in the efforts of missionaries to improve their physical and spiritual conditions of life

CIVIL SERVICE BONUS

The Ministry of Health gives notice that as from the beginning of the present month the Civil Service bonus will be on the basis of an average cost of living figure of 70 The bonus payable for the six months commencing Sept 1st, 1926, to officers whose salaries do not exceed £500 a year will therefore be one-eighth less than that payable during the preceding six months In the case of salaries over £500 a year the bonus will still be subject to the special arrangements made in 1921

OPHTHALMIC BENEFIT

Only a certain number of the approved societies have adopted the scheme by which their *members are entitled* to a consultation with an ophthalmic specialist for the fee of one guinea, *and since other societies continue to send their* members to opticians, it rests with the specialists concerned *to make their service so successful* that pressure from the members may lead to the general adoption of the scheme *It is essential* that the list of specialists should be carefully scrutinised, a task which we believe has so far been efficiently performed Further, it is essential that the principle of free choice should be maintained, and for this purpose that the insured person should have the opportunity of choosing a specialist from the list Full use of the scheme implies that no unnecessary difficulty will be put in the way of obtaining the necessary recommendation from the panel practitioner stating the need of advice by an ophthalmic surgeon

"£2000 REWARD"

The management of a well-known general hospital has received the following communication addressed "To the Governors"

> *(Confidential)*
>
> Two Thousand Pounds Reward
>
> I will *pay this amount to any* person who will *get me elected* as a surgeon upon the staff of a fairly large infirmary One thousand upon election, *the balance at the* year end (if I still hold the appointment)
>
> This is a bona fide offer
>
> I am anxious to become a "specialist" It is impossible or nearly so, to become a specialist unless elected to a hospital In a town of county borough size as a minimum as practically all the surgery is done in institutions
>
> *Please* use the personal column of the *Daily Mail* under pseudonym of "Lumbar Puncture" in answering in strictest secrecy

The first inference from the communication is that it is not written by a doctor, for no one conversant with *pro*fessional work would believe, even if they thought it possible to buy the post, that to be "a surgeon upon the staff *of* a fairly large infirmary" would ipso facto make the holder of the post a recognised "specialist." On the other hand, the communication may be, despite its odd and unprofessional form, the cry of a disappointed doctor who has some reason to believe that, given the opportunity, he would have made a name for himself as an operating surgeon, but who finds that the public in his particular environment prefer the services of those, possibly his seniors, who are upon the staff of the local hospital We are familiar with instances where this situation has been a hard one, but we know of *no instances where time and proven* merit have not come *to* the rescue

PUBLIC HEALTH IN THE TONGAN ISLANDS

A British *protectorate over the Tongan or* Friendly Islands was proclaimed in 1900 These islands are situated in the Southern Pacific to the *E S F of Fiji and 390* miles therefrom with an area of 385 square miles The estimated population in 1925 was 25,088, all *Tongans with the exception* of about 580 Europeans, 240 half-castes, and 370 natives of other Pacific islands For a long period of years there has been a steady increase in the population, the birth-rate per 1000 in 1924 was 35 9 and the death-rate 18 1 During the year a campaign against hookworm was undertaken The Board of the Rockefeller Foundation *lent* the services of an expert for a preliminary survey and to inaugurate the campaign The native population *responded* to mass treatment with gratifying results, and a beginning was made in the task of improving the sanitary *condition* of the villages and the water-supplies A standard type of fly-proof latrine was adopted and is now being *made* by the Government for sale to the natives The village water-supplies, consisting of large concrete cisterns, *are* being repaired and where necessary enlarged, and measures have been taken to ensure sufficient supplies of clean water *For eight* months of the year—from May to November—the thermometer rarely registers higher than 83° F, *and,* as *the humidity* is comparatively low during these months, Europeans do *not* feel the heat to the same *extent* as in *the groups of* islands to the north During the wet season—from December to March—the temperature ranges *from 65° to 94°,* with a higher humidity Malaria and other tropical fevers are unknown

English winter and, in fact, he does find it harder to keep well in England, although his general condition may have been much improved

For the average tuberculous patient it is an obvious advantage to receive his treatment in climatic conditions broadly similar to those in which he has eventually to return to work The less climatic difference there is between the place of treatment and cure and the place where work can be recommended the more lasting the cure will be This is in itself a general argument against prolonged Swiss treatment, for to become acclimatised to altitude is to become *de*climatised to English conditions and makes resumption of work so much the harder and the more precarious

Thus, whilst a single year or 18 months in Swiss altitudes need not produce any serious declimatisation, continuous treatment there beyond that period, or regular return throughout each winter for several years, makes it more and more impossible for the average quiescent type of case ever to resume steady work in this country Once again, Swiss treatment is suitable for the man of independent means who can live where he likes, when he likes, but has its dangers for the average man who has to work for his living

SOME RESULTS OF STUDIES IN THE PHYSIOLOGY OF POSTURE

Delivered at the University of Edinburgh, May 19th and 20th, 1926,

By RUDOLPH MAGNUS,
PROFESSOR OF PHARMACOLOGY, UNIVERSITY OF UTRECHT

Part II *

B General Static Reactions of the Mid-brain Animal

After cross-section through the calamus scriptorius the animal behaves like a spinal preparation without static functions (only the tonic neck reflexes are present), if under the influence of one or other stimulus the muscles get some "background-tonus," the change of such tone after turning of the neck can be demonstrated After a cut just in front of the entrance of the eighth nerves the animal shows decerebrate rigidity and has active tonic neck and labyrinthine reflexes The centres which give rise to the rigidity and the labyrinthine reflexes are situated in the caudal part of the medulla oblongata They are including their afferent and efferent paths, extracerebellar

This picture remains in the main unchanged if the cutting of the brain-stem is performed more orally Then also reflexes on the abducens and trochlearis nerves and neck righting reflexes appear, but the general condition remains the same The latter does not change fundamentally, until the cut is made through the most oral part of the mid-brain in rabbits and cats through the foremost half of the anterior colliculi and in front of the origin of the oculomotor nerves The condition of the animal is then no longer "decerebrate" but becomes "normal" The difference is caused by the absence of rigidity, the appearance of a normal distribution of tone, and the presence of the righting function That means that the animal is able from all abnormal positions by its own active movements to right itself into the normal position and to keep this position against all disturbing influences

If the cuts are made more orally, no *essential* differences in the static behaviour can be observed It makes no appreciable difference in the static behaviour whether the basal ganglia are present or have been extirpated If the fore-brain is left intact the influence of optic stimuli upon posture in some species of animal can be demonstrated Extirpation of the cerebellum gives rise to very characteristic symptoms, but all the static reactions which are described in these lectures are present, and can still be evoked with great certainty Some of these reactions seem to be exaggerated in the decerebellated animals

The most convenient way to study all static reactions of the mid-brain animal is to prepare a thalamus preparation Then the heat regulation is undisturbed, the function of the mid-brain centres is not greatly interfered with by operative shock, and in consequence of the absence of the fore-brain no voluntary movements disturb the observation It is clear, however, that control experiments on mid-brain animals should always be made For this purpose the rabbit, which is very resistant to shock, should be chosen

1 *The Normal Distribution of Tone*

The distribution of muscle tone in the whole body musculature in the mid-brain and thalamus animal differs from that in the decerebrate preparation by the absence of the exaggerated enduring contracture of the static muscles These have only just sufficient tone to carry the weight of the body and to balance it The result is the "normal" attitude and posture of the thalamus, as compared with the "caricature" attitude of the decerebrate preparation

In the former even slight muscular actions are sufficient to change the position of the body

While in the decerebrate preparation the flexor muscles are completely deprived of tone, they are in the mid-brain animal just as much under tonic innervation as they are in the normal animal In consequence of this the flexor muscles participate much more in all sorts of reflexes than they do in decerebrate rigidity Reflex inhibitions of flexor muscles can, on the basis of their "background" contraction, easily be demonstrated The experiments of Girndt have shown how the reflex behaviour of a thalamus animal is influenced by the presence of flexor reflexes

The attitudinal reactions of the thalamus and mid-brain animal differ also from those of the decerebrate preparation by the presence of flexor responses Changes in the position of the head, under decerebrate rigidity, give rise to reactions chiefly in the extensor muscles, whereas in the mid-brain and thalamus animal flexors and extensors are influenced simultaneously. The change of tone in the flexors and extensors follows the laws of reciprocal innervation, increased extensor tone being accompanied by flexor inhibition and vice versa This makes the static reactions more smooth and exact

After ordinary reflex excitations the extensor muscles do not show the prolonged after-effect of the decerebrate preparation, and this also prevents the appearance of stiff movements The decerebrate preparation shows no positive supporting reflex and only a very imperfect negative phase. The whole supporting reaction, which changes the limb from the movable and instrumental condition into a static support and vice versa, is only fully developed in the mid-brain or thalamus animal

All these observations show the fundamental part the mid-brain centres play in the whole static function It is to be expected that the study of the thalamus animal will disclose many interesting facts, and that, just as the last 20 years have with such great success been devoted to the study of the decerebrate preparation of Sherrington, in the next period the mid-brain animal must be the chief object for further careful analysis

2 *The Righting Reflexes*

Analysis has shown that the righting function is carried out by the cooperation of five groups of different reflexes It is, therefore, intelligible how it should be impossible to study the action of one of these groups by paralysing the sensory nerve-organs, from which this group of reflexes takes its origin The result of such a procedure would only be that the four other groups of reflexes would compensate for the loss of function so produced, and that probably no disturbance of righting would result Here, as in other complex functions of the central nervous system, it is not permissible to draw conclusions from the isolated paralysis of one set of reflex centres. A complete understanding of the whole mechanism is only possible if the experiment starts from the "zero condition" in which *all* centres or mechanisms concerned in this complex function have been paralysed, so that it is completely absent in the animal. Then in subsequent experiments one or another centre of sense organ may be spared and the function arising under this new condition compared with the "zero condition" It is thus possible to study every single reflex while excluding all others and, finally, to analyse the cooperation of these several reflexes towards a general function

(a) *The "Zero Condition"*

In the case of the righting reflexes the zero condition is fulfilled if a thalamus or mid-brain animal after extirpation of both labyrinths is held freely in the during normal respiration) in order to overcome this resistance

---

* Part I appeared in The Lancet last week

I do not know whether prolonged subjection to this positive pressure is capable of doing the delicate lung alveoli harm, but it is a fact that if this resistance to the return stream be removed the anæsthesia is very much quieter and more peaceful In order to overcome it I have resorted to the practice of double intubation—that is to say, side by side with the catheter a second and larger tube is passed by way of which the return stream will travel This is made of a special thin-walled, hard rubber which does not easily collapse, and is tied to the catheter and passed into the trachea with it Its advantages in producing quiet breathing, freedom of airway, however much the jaw be depressed, and in preventing bubbling of blood which often obscures the surgeon's view when only a single catheter is used, are so considerable that I am sure one is justified in using it in nearly every case In intranasal operations, for instance, the use of a post-nasal sponge becomes quite unnecessary.

OPERATIONS ON THE MOUTH, TONGUE, AND THROAT

When the mouth is the site of operation, the nose is chosen as the route for delivering the anæsthetic—the catheter being passed down one side and the return airway down the other. As a preliminary measure and before starting the anæsthetic, in order to prevent bleeding which may obscure one's view with the laryngoscope, it is advisable to spray the nose with adrenalin, or a mixture of cocaine and adrenalin The catheter and the return tube should be well lubricated with sterile vaseline to facilitate their passage through the nose

As originally described by me,[3] this method consists in passing the catheter through the nose, and then, by the aid of a direct laryngoscope and a special guiding rod, catching it up in the pharynx and directing it into the trachea; but with practice I have found that the catheter can nearly always be manipulated through the cords quite easily if it is stiffened by a wire stylet, and bent to form about half a circle With stylet in place it is passed down the nose and then, by direct vision, guided into the trachea. It does occasionally happen, however, that a deviate septum or an incorrect curve on the stylet will necessitate the use of the guiding rod, by means of which one can pick up the catheter at its eye and guide it between the cords The return tube has a stouter stylet which runs through a hole in the metal angle-piece at the top of the tube, and it can be moved from side to side in the pharynx by rotating the stylet which obtains some purchase on the metal angle-piece

I had a special guiding rod made to pick up this tube as one does the catheter,[4] and although generally the stylet is sufficient, on occasions it proves very useful In this way the air passages are shut off from the mouth, which can be full of blood without danger of any entering the trachea There are three sizes of return tube, which are chosen according to the size of the patient

It is in these operations about the mouth and throat (big dental extractions, tonsil dissections, excision of tongue, &c) that double intubation is especially useful, for not only is the anæsthesia tranquil, and the airway maintained, however much the jaw be depressed, but the surgeon's work is not hampered by the constant need for swabbing away blood which has bubbled up from the mouth

Single Intubation

In the majority of cases I suppose an intratracheal anæsthetic is given, because by its use the airway can be controlled without holding up the jaw or otherwise handling the patient's head, and the anæsthetist can keep well out of the surgeon's way It is only in very few cases that a positive pressure is really necessary

It occurred to me that if one could pass a single tube of adequate size through the mouth (or nose) and into the trachea, and allow the patient to breathe backwards and forwards through it, a state of things much more akin to that which occurs during natural respiration would be achieved Moreover, the first part of the respiratory passages would be just as well cut out; and, provided the tube were sufficiently large to fill the glottic opening, there would be no danger of blood or other material entering the trachea This was found to be no more difficult than passing the smaller return airway for use with a catheter, in fact, the single operation takes less time A special stylet was made for controlling the tube when passing it through the mouth.

This single intubation has the added advantages that a rebreathing bag may be attached, and gas and oxygen given in the ordinary way—this gives a much more satisfactory anæsthesia, and also (when necessary for such cases as diathermy) chloroform from a Junker's bottle may be very easily administered through it

CHEST CASES

In operations where the pleural cavity is to be opened it is a great advantage to be able to control the collapse of the lung, and where necessary to keep it blown up This can be easily done by double intubation combined with some method of checking the return stream For this purpose a simple apparatus provided with a shutter and pressure gauge is connected with the return tube

We found first of all from our experiments on dogs, and later on when administering anæsthetics to human beings, that the symptoms of collapse from which patients suffer when a pneumothorax is first produced can be very largely prevented by maintaining a positive pressure in the lung of 15–20 mm Hg, and only reducing it very slowly should the surgeon require the lung to be collapsed

SUMMARY

(1) Intratracheal anæsthesia is the method of choice for all operations upon the head, nose, mouth or throat, where the anæsthetist cannot maintain a satisfactory anæsthesia and a free airway by the ordinary methods without seriously interfering with the surgeon

(2) When there is blood in the upper air passages it is a necessity—effectively preventing its entrance into the bronchi and air cells, and lessening the liability to pulmonary complications In double or single intubation we have a refinement which is of great help to the operator in shutting off the air passages and giving him a clear field for operating

(3) In intrathoracic operations where normal respiratory mechanism is interfered with, double intubation enables one not only to maintain respiratory exchange, but to regulate the collapse of the lung, and so save the patient much shock

[3] Brit Med Jour 1920, ii, 590

[4] Brit Med Jour, June 30th, 1923

ADVISORY COUNCIL FOR SCIENTIFIC AND INDUSTRIAL RESEARCH —Prof Vernon Herbert Blackman, Sc D, F R S, Prof Frederick George Donnan, C B E, D Sc, LL D, F R S, and Prof Frederick Alexander Lindemann, Ph D, F R S, have been appointed by Order of Council dated August 20th, to be members of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research, in the place of members who have retired on the completion of their terms of office

Mr Henry Kimpton announces the forthcoming appearance of a book on the "Surgical Treatment of Goiter," by Dr Willard Bartlett, with a foreword by Dr Charles Mayo, a fifth edition of Hajek's "Pathology and Treatment of the Inflammatory Diseases of the Nasal Accessory Sinuses," translated and edited by Dr Joseph D Heitger and Dr French K Hansel, and a manual of "Clinical Laboratory Procedure," for the use of the general practitioner, by Dr Robert A Kilduffe, city bacteriologist, Atlantic City

The easiest way to demonstrate these reflexes is to hold a normal animal in the lateral position in the air, the head also being kept firmly in the lateral position. In this condition the neck righting reflexes tend to keep the body in the lateral position. If now the animal is placed upon the table and the head kept continuously fixed in the lateral position, the body is seen to be righted into the normal position in spite of the tendency of the neck righting reflexes to keep the body on its side. The active stimuli for these reflexes arise in the sensory nerve-endings of the body surface, which are stimulated asymmetrically by the pressure against the ground. If by means of a weighted board the other side of the body is also pressed upon, the symmetry of stimulation is restored and the body therefore remains in the lateral position.

In climbing animals similar strong influences arise from the feet and hands, and cause orientation of the body towards trees, walls, roofs, &c.

(*f*) *Optical Righting Reflexes*

The four groups of above-described reflexes are the only righting reflexes of the thalamus animal, and also of intact rabbits and guinea-pigs. In higher mammals such as cats, dogs, or monkeys with intact cerebrum the eyes contribute towards the orientation of the head. In order to study these reflexes the delabyrinthised animals must be examined freely in the air. Then it can be seen that the head, if blindfolded, is completely disorientated and shows no correction from any abnormal position. If the eyes are opened, the head is brought into the normal position as soon as the visual attention of the animal is attracted, and it fixes with its eyes something in its environment such as food, a fly, the assistant, &c. If this visual attention ceases, the head may go back into any abnormal position.

The exact position of the centres for these reflexes has not yet been determined. It may be supposed that they are localised in the optical cortex.

All these reflexes coöperate in the intact animal, and enable the body to attain and to keep a certain position. If the animal is moving on the ground all these reflexes coöperate in the same sense, but if the animal is climbing a vertical surface or beneath a horizontal roof—i e, of a cage—sometimes conflicting influences come into play and lead to interesting results.

The integrity of every single factor of this complicated function is doubly ensured. The head is righted by labyrinthine, tactile and optical stimuli; the body by proprioceptive and tactile stimuli. The tactile stimuli act separately upon the body and upon the head. The orientation of the head and of the body takes place in relation to gravity, sustaining surface (ground, &c), distant environment (optical) and to parts of the body—a very complex combinátion of reflexes. It is indeed an interesting task to watch the coōperation and interference of these reflexes during the movements of various animals in their ordinary life.

3 *The Centres for the Righting Reflexes.*

The position and distribution of the centres for the righting reflexes have been determined by Rademaker. In a great number of experiments with cats and rabbits he made transverse sections through the brain-stem at different levels, determined those reflexes which were present after recovery from the shock of the operation and those which were absent, and made in every case a careful histological examination of a complete series of microscopical sections. A synopsis of all experiments showed the most caudal level for each reflex at which a transverse section of the brain-stem did not interfere with its function. The conclusion could then be drawn that the centres of that special reflex must, together with the afferent and efferent paths, be situated caudally from this level. Then cutting across somewhere behind this level led to the disappearance of the reflex. In this case the conclusion that the centre must be situated orally to this level cannot be drawn with absolute certainty, because it is always possible that the centre lies behind the cut, but is thrown out of action by shock or diaschisis. In this way it was found by Rademaker that section through the anterior part of the anterior colliculi and just orally from the points of origin of the third nerves does not interfere with the presence of normal labyrinthine and body righting reflexes, whereas a section carried out some millimetres more caudally—i e, behind the origin of the third nerves—destroys the above-mentioned righting reflexes. In the latter case the neck righting reflexes are still present. Their centres are arranged more caudally in the pontine region. Extirpation of the dorsal half of the mid-brain does not interfere with the presence of the righting reflexes. Total extirpation of the cerebellum leaves all righting reflexes, including the body righting reflexes, intact. By these experiments it is proved that the centres for the righting reflexes lie in the ventral part of the mid-brain behind a section just in front of the third nerves. The disappearance of the labyrinthine and body righting reflexes after cutting the mid-brain behind the third nerves suggested the possibility that the centres for these reflexes were situated just at the level of the oculomotor nerves. The most remarkable nucleus here is the red nucleus, the magno-cellular part of which gives origin to the rubro-spinal tract, which crosses at about the same level in the decussation of Forel. As median sagittal splitting of the mid-brain destroys the righting reflexes in question, the probability is increased that the red nuclei are the centres sought for. Therefore Rademaker proceeded to make dorsal or ventral median incisions into the mid-brain, which divided it just deeply enough to leave Forel's decussation undisturbed. Animals with such incisions showed the righting reflexes. But as soon as the cut was made a little deeper, so that the rubro-spinal tracts were severed, the labyrinthine and the body righting reflexes acting upon the body disappeared. Other experiments of Rademaker showed that the righting reflexes were normally present after the destruction on both sides of the substantia nigra and the pyramidal tract. Also lesions lateral to the red nuclei did not prevent the appearance of the righting reflexes. By all these experiments it is proved that in the cat and rabbit the red nuclei are the centres for the labyrinthine righting reflexes and the body righting reflexes which act upon the body. The efferent path for these reflexes is the rubro-spinal tract. The *body righting reflexes acting upon the head* have their centres at the same level but not in the red nuclei. The centres for the optical righting reflexes are cortical, the centres for the neck righting reflexes lie more caudally in the pontine or upper bulbar region. The exact course of the afferent paths for all these reflexes is still to be determined. It is only known that they do not pass through the cerebellum.

In the thalamus animal extirpation of the red nuclei or isolated severance of the rubro-spinal tracts causes still another change. It leads to the disappearance of the normal distribution of tone and the appearance of decerebrate rigidity. The presence in the thalamus animal of rubro-spinal impulses counterbalances the influences from the centres in the lower bulbar region, which, if acting alone, cause the extensor tone to be greatly increased with diminution of flexor tone.

The following experiment of Rademaker's was very striking. In a thalamus animal a thread was drawn through the medial plane of the mesencephalon in the dorso-ventral direction just behind Forel's decussation. The animal showed normal distribution of tone, all righting reflexes, and normal sitting and running. Then slight traction was applied to the thread just sufficient to divide the rubro-spinal decussation. The result was maximal decerebrate rigidity, paralysis of the labyrinthine righting reflexes, and the body righting reflexes acting upon the body.

While in the thalamus animal cutting of the rubro-spinal tract causes such marked effect, in the normal animal with intact fore-brain the same operation has much less drastic consequences. The extensor tone air without touching the ground Then no attempt will be made by active movements to bring the head or the body into the normal position If the animal is held by the pelvis in the lateral or supine position the whole body, including the head remains also in this position The " zero condition " of animals with *intact* cerebrum differs according to species Rabbits and guinea-pigs, in which the eyes are not used for righting purposes, if delabyrinthised and held freely in the air, show no righting reflexes Cats, dogs, and monkeys, on the other hand, must be also blindfolded

Under all these conditions the animal is completely disorientated and cannot bring its head or body into the normal position

(*b*) *Labyrinthine Righting Reflexes*

If their labyrinths are intact then all thalamus animals as well as normal rabbits and guinea-pigs and blindfolded normal dogs, cats, and monkeys, when investigated freely in the air, show the following reflexes —

If the animal is held by the pelvis in the normal position the head also assumes the normal position If the pelvis is held in the lateral position the head is by rotation brought into the normal position It is possible to turn the pelvis from one lateral position into the other, while the head remains in the normal position In whatever position the pelvis be supported—e g , supine or vertical with the head above or below—the head itself is always held in the normal position

These reflexes act primarily on the neck muscles They are originated in the labyrinths and disappear after labyrinth extirpation They also disappear after detaching the otoliths by centrifuging For the discussion as to which otolithic maculæ are responsible for the labyrinthine righting reflexes we must divide these reflexes into two groups

1 The *asymmetrical righting reflexes* bring the head from asymmetrical—e g , lateral—positions into symmetrical positions about a vertical plane

2 The *symmetrical righting reflexes* provide that out of all possible symmetrical positions the normal position is taken.

The asymmetrical righting reflexes are evoked from the maculæ sacculi This is proved by the fact that after unilateral labyrinth extirpation the resting position of the head is no longer the normal position, but the lateral position . from which it must be concluded that the maculæ concerned cannot lie in one plane, so that the utricular maculæ cannot be responsible for these reflexes The asymmetrical righting reflex after unilateral labyrinth extirpation is very strong, if the head is kept in the lateral position with the intact labyrinth below , then the saccular otolith pulls on the macula The head comes to rest and the reflex therefore reaches its minimum, if the intact saccular macula lies horizontal with the otolith pressing upon it In this case therefore it can be proved that the maximum of stimulation in the macular epithelium must be evoked by the pulling, and the minimum stimulation by the pressing otolith The utricular maculæ are probably the point of origin of the symmetrical righting reflexes. This has been concluded from experiments, in which the labyrinths of guinea-pigs have been paralysed step by step with cocaine, so that first the saccular and then the utricular reflexes disappeared, while the reflexes from the canals preserved their function for some time longer

In every case the symmetrical righting reflexes bring the head into such a position that the utricular maculæ lie horizontally, so that the otoliths press upon the sensory epithelium This reflex then reaches its minimum and the head comes to rest

The labyrinthine righting reflexes provide for orientation of the head in relation to space, gravity being the controlling influence

(*c*) *Body Righting Reflexes Acting upon the Head*

For an isolated demonstration of these reflexes we start again from the " zero condition," and hold a labyrinthless thalamus or intact animal (blindfolded or not according to the species) freely in the lateral position in the air Then the head also will be in the lateral position. We now place the animal upon the table, and notice that immediately after the body of the animal comes into contact with the ground the head is rotated towards the normal position This reflex is evoked by the asymmetric stimulation of the pressure sense organs on the body surface This can be proved by compensating for the asymmetry of stimulation—e g , by placing a weighted board upon the upper side of the animal, so that the pressure upon each side of the animal is the same The head then falls back into the lateral position If the board is taken away the head is again righted If the animal then be lifted from the ground, the head returns to the lateral position These observations show the importance of tactile stimuli for the orientation of the head By these influences the head is orientated in relation to the ground or other surfaces with which the body of the animal comes into contact Reflexes of this sort can be evoked not only from the surface of the trunk but also from the soles or palms In this way the heads of climbing animals, such as monkeys, squirrels, &c , are orientated towards the objects upon which the animal is climbing

These reflexes also play a rôle in the correction of abnormal positions of the head After unilateral labyrinthectomy the rotation of the head towards the operated side, which is often very distinct, becomes greatly diminished if the animal be placed on the ground

In this way two active influences cooperate in righting the head the one in relation to gravity, the other in relation to the ground

(*d*) *Neck Righting Reflexes*

The neck righting reflexes orientate the body in relation to the head When, by the combined action of the labyrinthine and body righting reflexes, the head is restored to the normal position, while the trunk still remains in the original abnormal position (e g , the lateral), then the neck is twisted This evokes a reflex by which the thorax is brought into symmetry with the head This may give rise to a rotation of the lumbar region, which in turn causes a similar reflex upon the hind part of the body, so that finally the whole body has followed the head into the normal sitting position In a similar way dorsiflexion of the head gives rise to lordosis of the whole vertebral column Ventroflexion is followed by a curving of the whole body in the ventral direction Inclination of the head towards one shoulder evokes curving of the vertebral column with the concavity to this side

All these influences can be immediately seen if an intact animal be held freely in the air with the pelvis in all different positions The head is then primarily brought into the normal position, and the fore-part of the body follows the head, whereas the pelvis is prevented from doing so by the hand supporting it Several of these reflexes can easily be demonstrated in the supine position of the animal , movements of the head in different directions evoke in this position very marked reactions upon the hind part of the body The neck righting reflexes make it possible, by simple movements of the head, to bring the body of even very strong animals on its side

(*e*) *Body Righting Reflexes Acting upon the Body.*

The neck righting reflexes ensure the orientation of the body in relation to the head , the body righting reflexes right the body in relation to the ground (or any surface with which the body comes into contact—e g , in climbing) These reflexes make it possible for the body to be righted, even if the head is not in the normal position

BLOOD-SUGAR IN THE NORMAL AND DIABETIC

BY C D SHAPLAND, M B, B S LOND,
RESIDENT PHYSICIAN, RUTHIN CASTLE.

AT one time it was believed that the blood-sugar concentration remained at a practically constant level, even a large carbohydrate meal producing no increase in the amount of circulating sugar Pavy was of the opinion that the liver prevented any rise in the blood-sugar concentration, and if for any reason the liver failed in its function and a hyperglycæmia resulted, the excess of sugar would be immediately excreted in the urine

In 1911, however, Baudouin[1] found that there was a slight increase in the amount of blood-sugar one hour after a meal, an observation which was confirmed and slightly extended by Frank[2] and Reicher and Stein[3] Two years later Jacobsen[4] showed that the rise in blood-sugar occurred much earlier than one hour after a meal, and indeed, might be present within five minutes of a dose of sugar, a maximum concentration was usually reached in from 15 to 30 minutes after the dose of sugar, and in seven cases the blood-sugar had returned to its original level after 60 minutes These observations have been confirmed by Bang, Graham MacLean, and many others, and, during the last five years, the changes in blood-sugar concentration following the ingestion of a definite quantity of carbohydrate have been found of practical value in the diagnosis of early mild cases of diabetes and anomalous types of glycosuria

The changes in blood-sugar concentration which occur in youth, old age, in diabetes and obesity after the ingestion of a fixed quantity of cane sugar are dealt with in the first part of this paper In the second part the daily variations of the blood-sugar seen in normal and diabetic individuals on weighed diets are described and illustrated

TEST BLOOD-SUGAR CURVES AFTER INGESTION OF CANE SUGAR

(a) *Method*

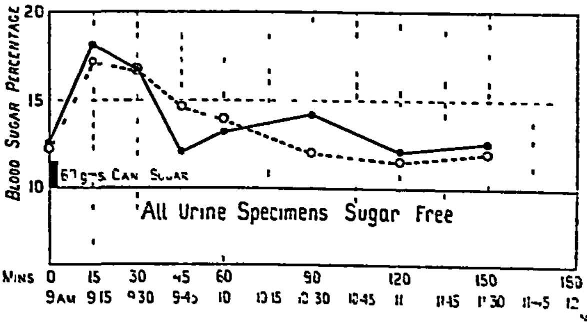
The blood-sugar curves were obtained in the following manner After the subject of the experiment had fasted for about ten hours the bladder was emptied and the urine collected, at the same time 0 2 c cm of blood was taken for sugar estimation, 60 g of cane sugar dissolved in 6 oz of water flavoured with lemon-juice were given, and thereafter samples of blood were taken every 15 minutes for the first hour and at half-hourly intervals for a further two hours The urine passed at the end of each hour was tested for sugar with Fehling's solution, and if present, its quantity determined gravimetrically The sugar in the blood samples was estimated by MacLean's method When the results are graphically recorded the variations form a blood-sugar curve

(b) *Curves in Health*

Fig 1 shows the effect of the ingestion of 60 g of cane sugar on the blood-sugar concentration of a *healthy young adult* From the resting level of 0 12 per cent the blood-sugar rises rapidly to 0 18 per cent, this maximum being attained in 15 minutes after taking the sugar The blood-sugar now begins to fall, and after 45 minutes is even lower than the fasting level Following this stage there is a slight secondary rise before the blood-sugar settles down to its normal fasting level All the urine specimens from this subject were sugar-free

Fig 1 shows also the average blood-sugar curve (dotted line) obtained from *ten healthy individuals* whose ages ranged from 20 to 40 years The curve displays the same general features as the previous curve From the resting level of 0 12 per cent the blood-sugar concentration rises quickly and attains its maximum of 0 17 per cent in 15 minutes The time taken to attain the highest point may sometimes be increased, according to MacLean[5] the highest figure may not be attained until as much as one hour after taking the sugar, but in this series the longest time in a healthy adult under 40 years of age has been 45 minutes Variations, no doubt, depend mainly upon inequalities in the digestive functions, such as the rate of discharge of the sugar through the pyloric sphincter, the volume of the intestinal contents, the extent and nature of bacterial digestion, and the rate of absorption, but, speaking generally, in healthy subjects the highest blood-sugar reading should occur within an hour of taking the sugar The maximum concentration attained varies a good deal; the highest in this series were 0 20 per cent, the lowest 0 16 per cent, a good average being 0 17 to 0 18 per cent Naturally, as the blood-sugar concentration is changing from minute to minute it is a matter of chance whether one of the quarter-hourly samples coincides with the point of highest rise or not

FIG 1



Sugar tolerance test The continuous line shows curve from normal subject the dotted line is a composite curve from ten healthy subjects aged 20–40 years

Immediately after the maximum figure is reached the blood-sugar begins to fall, and this fall is almost as rapid as the initial rise, so that in a healthy young subject the blood-sugar is usually little above the fasting level some 90 minutes after the ingestion of the sugar, frequently, indeed it is even below the original level at this time In this series (Fig 1) the shortest time for the blood-sugar concentration to swing back to its fasting level was 45 minutes, the longest 120 minutes, and the average time 90 minutes from the taking of the sugar All the urine specimens from these subjects were sugar-free

(c) *Curves in Diabetes*

In *diabetes* the blood-sugar curve is of a very different type Fig 2 shows such a curve, taken from a case of moderate severity. The blood-sugar rises from the raised fasting level of 0 15 per cent and reaches the high maximum of 0 33 per cent. after 45 minutes Thereafter the fall is gradual, even after three hours the blood-sugar has not fallen to its original level Sugar appeared in the urine, 2 8 g being present in the first hour's specimen, 2 5 g in the second, and rather less than 0 2 g in the third.

In Fig 2 the dotted line represents a composite curve obtained from *ten diabetic patients* aged 20 to 60 years The typical features of a diabetic blood-sugar curve are well shown Starting from the raised fasting level of 0 17 per cent the blood-sugar rises steadily until, after 45 minutes, it has attained the high maximum of 0 29 per cent The point of greatest concentration was reached at its earliest in 30 minutes, at its latest in 90 minutes, the average interval being 45 minutes from the ingestion of the sugar The highest blood-sugar reading at the period of maximum rise was 0 39 per cent, the lowest 0 22 per cent, and the average 0 29 per cent, but the actual height to which the curve rises depends not only on the severity of the disease and the quantity of sugar ingested, but also on the height from which the curve starts and whether this fasting level has been reduced or not by is, however, increased, but much less so than in the thalamus preparation Only if, in addition to the rubro-spinal bundles, the pyramidal tracts are also severed, does there follow a marked increase of extensor tone The pyramidal tract has the function of partly counterbalancing the influence exerted in the spinal cord by the hind bulbar centres, which tend to increase the extensor tone We see thus that the tone and excitability of the spinal centres is governed by influences arising in the brain, a part of these tending to shift the mechanism in the direction of increased extensor tone, another part counterbalancing this influence with the result that both groups of muscles get equally their right share

4 *Righting Reflexes in Man*

The study of righting reflexes in man is still in its infancy. We know that these reflexes are present here also, but a careful analysis along the lines shown by animal experimentation has not yet been carried out, and not much is known about the way in which they cooperate towards providing the erect posture Landau, Schaltenbrand and others have begun the study in children during their first developmental stages, in which they acquire the erect posture and learn how to stand and to walk. Only when this pioneer work has been accomplished will an understanding of pathological conditions be possible

Labyrinthine righting reflexes can be demonstrated in children who are blindfolded and held by the pelvis in different positions in the air The head can then be seen to be moved towards the normal position (Schaltenbrand)

Neck righting reflexes are very active in man In children they have been studied by Landau, who showed that babies in the prone position usually bring the head by dorsiflexion into the normal position, and this is followed by strong lordosis of the vertebral column with extension of the limbs Passive ventroflexion of the head causes disappearance of the lordosis so that the whole body becomes ventrally concave Schaltenbrand published photographs of babies in which rotation of the head causes the body to roll from the supine into the lateral position, a reflex which, according to Zingerle, can be demonstrated in many patients Text-book photographs of gymnasts give ample evidence of the presence of similar neck righting reflexes in normal adults

Our own experience teaches that the optical righting reflexes in man play a very important rôle Of this many examples could be given It is sufficient to remember that in aviation the exclusion of visual impressions when the aeroplane is passing through mist or clouds makes orientation practically impossible Often when the aviator emerges from the clouds and can once more see the ground, he finds that he has been completely disorientated with respect to the earth

The " zero condition," in which all righting reflexes are suppressed, is realised if labyrinthless deaf-mutes are submerged under water Then no body righting reflexes can be evoked, optical orientation is absent, and the labyrinths are functionless As a consequence of this such patients will be drowned if no care is taken to help them out of the water

Experiments of Garten and his pupils on an inclining chair clearly demonstrated the great influence of the body righting reflexes evoked by the contact with the surface of the seat Even when labyrinthine impulses were made as ineffective as possible and the eyes were closed, there was a very precise estimation of the smallest deviations from the horizontal plane It is a pity that his early death prevented Garten from completing this research and from placing his experimental subjects under " zero conditions "

As to the relative influence of the different sensory organs for orientation it can be said that optical and tactile influences play a very important rôle in man, whereas the part played by the labyrinths is probably less than in rabbits and guinea-pigs These observations tend to show that in the mammalian series the rôle of the labyrinths decreases

Final Remarks

In concluding, I wish to draw your attention to the fact that the whole righting apparatus, with the only exception of the cortical centres for the optical righting reflexes, is arranged subcortically in the brain-stem, and in this way made independent of direct voluntary influences The attitudinal as well as the righting reactions are involuntary If under the influence of cortical impulses the normal position of the body be disturbed, the brain-stem apparatus is ready to restore it, so that every new cortical action finds the body in a normal starting position without previous voluntary effort

By the action of the subcortical mechanisms described in these lectures the different sense organs are always brought into the normal relation with the external world For the nerve-endings in the skin this is accomplished by the action of the above described attitudinal and righting reflexes In the case of the eyes a very complicated reflex mechanism has been developed differing in various species of animals, which regulates the position of the eyes in relation to the environment Here also labyrinthine and neck reflexes come into play The result of all these arrangements is that the sense organs are righted in relation to the external world, so that every sensory impression, before being transferred to the cortex cerebri, has already acquired a certain special condition (local sign) depending on the previous righting functions acting upon the whole body or parts of it In this way the action of involuntary brain-stem centres plays a very important part in conscious activities, especially as regards spatial sensations

All these things have not yet been worked out in detail, and as these lectures are addressed to an audience of students I am glad to say There is work enough left for you to do !

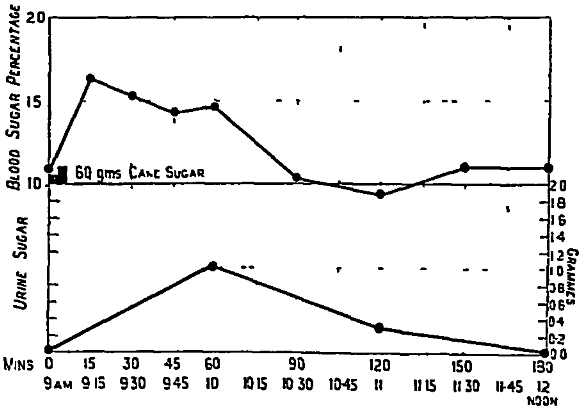
dextrose is absent from the urine of normal individuals is accepted If, on the other hand, the views of Benedict and Osterberg,[11] who find that dextrose is constantly present in normal urine in amounts up to 0 1 per cent , are held, then there is no absolute renal threshold, and the latter must be defined as the critical point in blood-sugar level below which the sugars of blood and urine run parallel, above which a large excess of sugar escapes into the urine (Macleod)

Whichever view is held there is no doubt that above a certain level of blood-sugar concentration a large amount of sugar appears in the urine , this generally lies in health between 0 16 and 0 18 per cent for the whole blood, and somewhat higher, about 0 19 per cent , for the plasma The figure varies in different individuals and, in this series, averaged between 0 18 and 0 20 per cent for the whole blood A difference is often observed in the threshold value if the latter is determined both on the basis of a rising and descending curve of sugar concentration in the blood Thus in Fig 3 sugar did not appear in estimable quantities in the urine until the blood-sugar concentration had reached 0 21 per cent , whereas it was still being excreted when the blood-sugar had fallen to 0 16 per cent This phenomenon is of practical importance, and, according to John, "glycosuria must be interpreted not only in its relation to the synchronous blood-sugar content and to the level of kidney permeability to sugar, but also in its relation to the blood-sugar variations during the preceding period during which the urine was secreted "[12]

A striking phenomenon in the curve of the healthy subject (Fig 3) is the intervention of the storage mechanism directly the blood-sugar concentration approaches the normal renal threshold for sugar This storage mechanism is so efficient that even if sugar ingestion is pushed to the limit of digestive tolerance it is rarely possible to produce a demonstrable glycosuria in a normal individual It is, indeed, doubtful if alimentary glycosuria can occur in perfect health , should it occur in a subject with a normal renal threshold for sugar, it indicates a defect in dealing with excess of carbohydrate and, therefore, the patient should be regarded as a potential diabetic.

In many cases of diabetes—in my experience especially the more severe—the renal threshold may be raised This elevation of the threshold of the kidney for sugar was at one time looked upon as a protective adaptation, limiting as it does the amount of sugar lost in the urine Nowadays, however, it is generally regarded as being disadvantageous to the patient, for the blood can contain more sugar than usual without its appearance in the urine Hence urine examination does not give a correct impression of the clinical condition With the urine containing little or no sugar dietetic restrictions are likely to be relaxed, hyperglycæmia, therefore, will probably occur more often, hyperglycæmia which is probably the cause, and certainly the concomitant, of many of the secondary changes and complications of the disease, and which taxes still further the already overworked and malfunctioning islet tissue of the pancreas

FIG 4

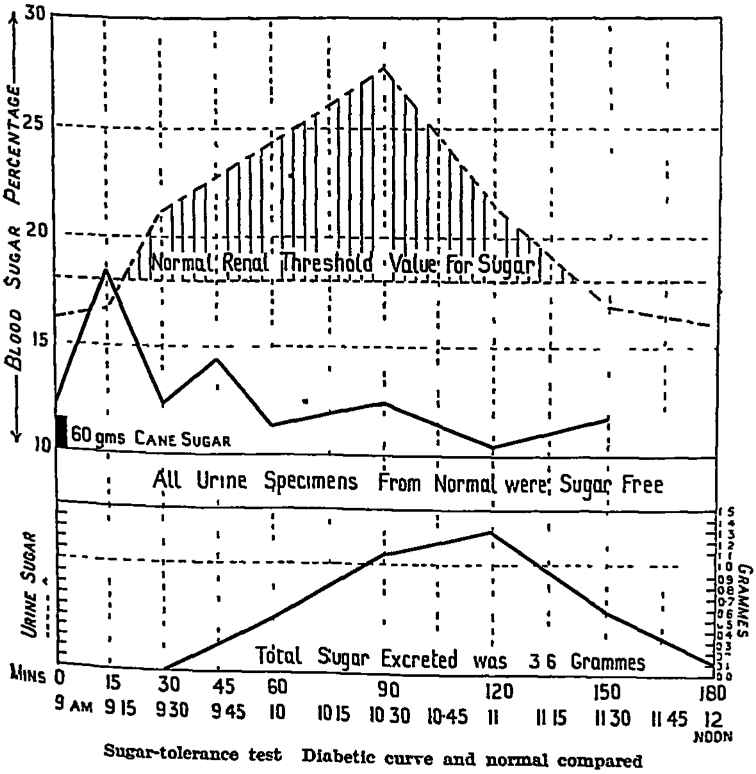


Sugar tolerance test Curve from a case of "renal glycosuria"

In a review of 50 cases of diabetes of varying severity Pickering[13] discusses various points connected with the renal threshold from a clinical standpoint He finds a greater proportion of high thresholds among the mild cases and suggests that a high renal threshold is not necessarily an unfavourable sign The threshold in his series, however, was not determined by blood-sugar curves, and a comparison of his results with those here recorded would not be strictly accurate

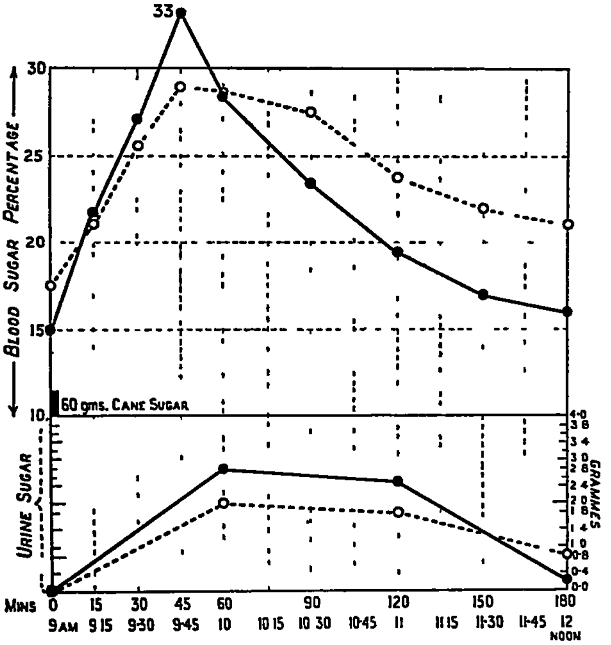
Just as the kidney threshold for sugar may under certain conditions become raised, so is there a clinical state in which the threshold is lowered This condition, which is generally known as "renal glycosuria," was described by Klemperer[14] in 1896 The number of cases reported has grown largely since blood-sugar observations became general in the investigation of glycosuria In most cases the patient is healthy, and the only abnormality discovered is a small amount of sugar in the urine, usually less than 5 g in the 24 hours Fig 4 shows a blood-sugar curve taken from such a case It presents the ordinary features of a normal blood-sugar curve, the only difference being the slight lowering of the point of maximum rise when compared with

FIG 3



Sugar-tolerance test Diabetic curve and normal compared treatment Following the attainment of the point of highest rise the blood-sugar concentration begins to fall, but the decline is slow and gradual, so that even after three hours it has not fallen to its original level In only one of these cases did the blood-sugar regain its fasting level in three hours, in the remaining cases the average estimation at the third hour exceeded the average fasting level by as much as 0 04 per cent

Fig. 2.



Sugar-tolerance test Continuous lines show curve from a diabetic subject the dotted lines represent composite curve from ten diabetic subjects aged 20–60 years

In each case the specimen of urine taken at the end of the ten hours' fast was sugar-free, but those taken at the end of the first, second, and third hours from the ingestion of the cane sugar all reduced Fehling's solution, an average of 2 0 g of sugar being present in the first specimen, 1 8 g in the second, and 0 8 g in the third

(d) *Comparison of Diabetic and Normal Curves*

When the blood-sugar curve obtained from a diabetic subject is compared with that taken from a young healthy individual (Fig 3) three important differences present themselves First, the blood-sugar concentration in the diabetic rises very much higher than it does in the healthy subject and far exceeds the normal renal threshold, secondly, sugar appears in the urine of the diabetic, but not in that of the normal; and lastly—most important of all—in diabetes the blood-sugar takes a very much longer time to return to its original level Briefly, then, the blood-sugar curve in health shows a rapid rise, an almost equally rapid fall, the maximum concentration does not exceed the renal threshold, and sugar does not appear in the urine, in diabetes, on the other hand, the rise is rapid but much more prolonged, the fall is gradual and long drawn out, the renal threshold is exceeded, and sugar appears in the urine

Certain features of these blood-sugar variations after taking sugar are not well understood. MacLean has discussed the mechanism fully and the following is based upon his views The rapid rise in blood-sugar concentration which occurs immediately after the ingestion of sugar is an expression of the fact that absorption into the blood stream is taking place rapidly and, for a while, keeps ahead of the mechanisms of storage and utilisation The fall, however, which follows in the normal curve so soon after the maximum concentration has been reached is more difficult to explain It cannot be due to diminution in the rate of sugar absorption, for in the diabetic the blood-sugar continues to rise—in this case for one and a quarter hours after that of the normal had begun to fall, the amount of sugar absorbed during this time being sufficient to raise the sugar content of the diabetic's blood by 108 mg per 100 c cm As the abrupt fall in the normal curve cannot be ascribed to the cessation of absorption it may be due to (1) the sugar being excreted by the kidneys, (2) a sudden rise in the katabolism of sugar, or (3) the sugar being removed from the blood and stored more quickly than it is absorbed The first alternative can readily be excluded, for all the urine specimens from the normal subjects were sugar-free during the course of the experiment With regard to the second, there is no doubt that some of the sugar is burnt at once, for it is well known that both heat production and the respiratory quotient rise immediately after a carbohydrate meal, remain raised for some five or more hours,[6] and then gradually fall In this case, however, the rise and fall in blood-sugar concentration was over in one hour from taking the sugar, if the whole of the latter had been completely metabolised in that time it would represent the utilisation of about 240 calories in one hour from carbohydrate alone As the subject lay quietly in bed it is hardly possible that this quantity of sugar could have been burnt up in so short a time Moreover, Johansson[7] has shown that after the ingestion of 200 g of glucose the rise in carbon dioxide output lasts as long as six hours before falling to the fasting basis Hence some of the sugar must have been stored in the body

The rapid fall in the normal blood-sugar curve which occurs so soon after the maximum has been attained must be assumed, therefore, to be due to the sudden intervention of a storage mechanism, the activity of which is so great that the later stages of absorption are completely masked by it In the diabetic patient, on the other hand, this mechanism is absent or deficient The diabetic curve is, therefore, a truer picture of the rate of absorption than is the normal, though the result is complicated by a loss of sugar in the urine and by a certain amount of sugar katabolism

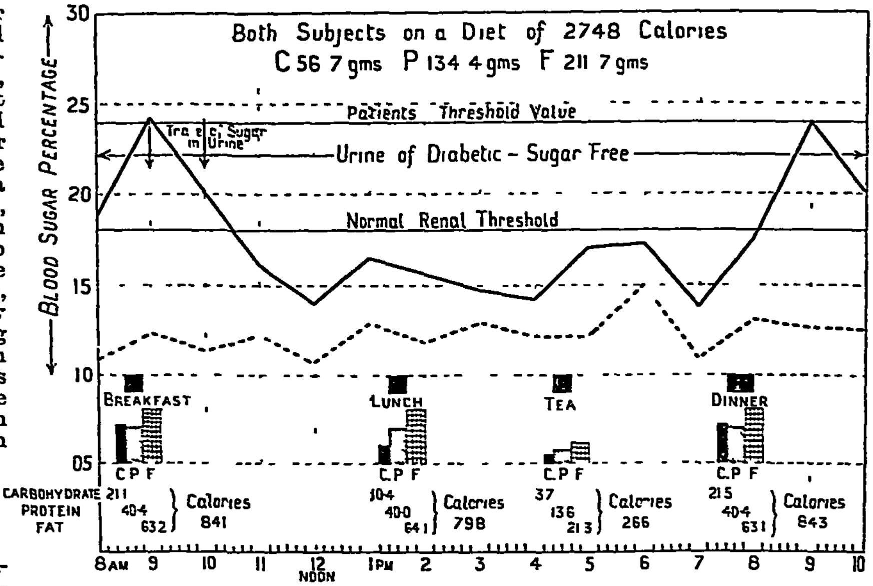
The muscles and liver are the main sugar store houses of the body, in diabetes the ability to store and to utilise sugar is defective or absent An immense amount of work has been done during the last decade on the question of sugar storage and the relative parts played by the liver, muscles, and pancreas The whole question is most complex, but "since glycogen is stored in the liver of depancreatised dogs following the administration of carbohydrate and insulin, and since the respiratory quotient under the same conditions will rise markedly, it is, therefore, evident that the beginning and end of carbohydrate metabolism is dependent upon insulin" (Joslin)[8] It may be assumed, therefore, that just as the prolongation of the blood-sugar curve in diabetes is due to a deficiency in the internal secretion of the pancreas, so is the rapid fall in health dependent on the integrity of the pancreas and its hormone The exact way in which insulin acts is not yet clear, the experiments of Buchner and Grafe,[9] who found that there was a rise in the oxygen consumption and respiratory quotient of thin slices of various tissues in an oxygenated Ringer's solution containing glucose when insulin was added thereto, show that insulin has an action upon all the organs of the body It is probable, however, that insulin acts chiefly in the liver and the muscles, its action being of an oxidative-synthetic character which leads in part to the formation of glycogen together with hexose phosphate and intermediate sugars from glucose, and also to an oxidation of the latter[10]

Another point of interest shown in Fig 3 is the leakage of sugar which occurs in the diabetic when the renal "threshold" is exceeded By the "threshold" of the kidney for sugar is meant the percentage level of sugar in the blood above which an amount of sugar recognisable by clinical tests appears in the urine, this definition is only strictly correct if the view that

MacLean has shown that the ingestion of 20 g of glucose will produce as high a degree of hyperglycæmia as will a dose of 50 g, but the 21 g of carbohydrate taken by this subject at breakfast and dinner were mixed with 40 g of protein and 63 g of fat, which would retard the processes of digestion and absorption The blood-sugar of the normal, even on this low carbohydrate diet, showed a substantial rise—to 0 15 per cent—after tea, this was followed by a rapid fall and then a slight elevation after the evening meal

The variations in the blood-sugar concentration of the diabetic (who was then an early mild case of *three months'* duration, and had received dietetic treatment only) were much greater Starting from the high fasting level of 0 19 per cent. the blood-sugar rose rapidly to over 0 24 per cent directly after breakfast and then gradually fell until, by noon, it had dropped to 0 14 per cent There was then a slight rise, but lunch produced no effect on the blood-sugar, which slowly fell during the afternoon until tea was taken, there was then an elevation which reached its maximum at 6 P M Dinner, just as breakfast, produced a great rise, the maximum concentration of 0 24 per cent being attained at 9 P M, one hour after the completion of the meal The blood-sugar then began to fall but at 10 P M, when the observations were concluded, it was still high—namely, 0 20 per cent All urine specimens from the normal subject were sugar-free, as were those from the diabetic with the exception of the specimens at 9 and 10 A M, each of which contained a trace of sugar

FIG. 5.



Blood sugar variations of a diabetic compared with that of a normal individual

(*d*) *Effect of Insulin on the Daily Variations*

The variations in blood-sugar concentration of a healthy subject aged 24 years and a young diabetic aged 21 receiving insulin are described here in illustration Both individuals were put on the diet of reduced carbohydrate value which was given to the subjects of the previous two observations, and blood-sugar estimations were made hourly throughout the day and night for a total of 23 hours Urine specimens were collected hourly during the day and twice during the night—at 2 and at 5 A M.

The normal curve started from a fasting level of 0 13 per cent and showed a slight rise followed by a rapid fall after breakfast Thereafter lunch produced a small elevation with a gradual fall during the afternoon, tea resulted in a greater rise, which reached its maximum about 6 P M, but even the figure at this hour was little higher than the fasting one at 8 A M Dinner had scarcely any effect on the blood-sugar concentration, which afterwards fell slowly until 1 A M, then remained fairly stationary for about three hours and rose again slightly towards 5 A M As would naturally be expected, the average blood-sugar level during the night was slightly less than the average level during the day, the latter figure (from 8 A M to 9 A M inclusive) being 0 124 per cent, the former (from 10 P M to 6 A M inclusive) being 0 118 per cent

The variations in the blood-sugar concentration of the diabetic, a case of moderate severity treated for a month with insulin, were much greater Starting from the high fasting level of nearly 0 24 per cent the curve rose, despite the 12 units of insulin which had been given at 8 A M, to 0 30 per cent, but then a rapid fall occurred so that the low figure of 0 11 per cent was reached at noon, this rapid drop being due to the action of the insulin injected at 8 A M. After lunch there was a steady rise in blood-sugar, which was quickened after tea, and had reached its maximum at 6 P M A further dose of 12 units of insulin was given at 7 P M, and this effectively checked the usual after-dinner rise, the blood-sugar concentration falling uninterruptedly until midnight There was then a slight secondary rise with a drop at 4 A M., after which the curve rose and was still rising when these observations were concluded All urine specimens from both subjects were sugar-free with the exception of those at 9 and 10 A M from the diabetic which together contained about 1 1 g of sugar

CONCLUSIONS

(*a*) Cane sugar or sucrose when ingested on an empty stomach by a healthy young subject produces in suitable quantities a definite blood-sugar curve which is similar to that given by glucose when taken in similar amounts under the same conditions

(*b*) Cane sugar in the diabetic subject under these conditions produces, like glucose, a blood-sugar curve which differs materially from that seen in health

(*c*) These curves are of value in the diagnosis of anomalous types of glycosuria

(*d*) Both in advanced years and in obesity of long standing the blood-sugar curve tends to approach the diabetic type, in early cases of obesity, however, the carbohydrate tolerance is sometimes increased.

(*e*) In diabetes—especially the more severe cases—the renal threshold for sugar tends to become raised.

(*f*) The blood-sugar variations during the day on an ordinary diet may in health amount to as much as 0 078 per cent of sugar The main elevations in blood-sugar concentration are seen after the meals containing the bulk of the carbohydrate of the diet, but a secondary elevation tends to occur towards the late afternoon, a rise which may be associated with the slow production of sugar derived from protein metabolism

(*g*) The variations in blood-sugar concentration seen normally in health during the day occur also in diabetes, but in an exaggerated form These excessive that seen in most normal individuals after the ingestion of 60 g of cane sugar This is easily understood when it is considered that there is a loss of sugar in the urine directly the blood-sugar concentration rises above the lowered threshold level The patient from whom this curve was obtained is a young man aged 24, who, beyond some colic delay, is in good health On a diet of some 2200 calories with 200 g of carbohydrate he passes about 3 g of glucose in the 24 hours The urine does not contain albumin The glycosuria was discovered during a life insurance examination

(e) *Curves in Old Age and Obesity*

Turning once again to the blood-sugar curve in health it is of interest to note that whereas in infancy and up to 3 years of age the blood-sugar concentration (as Spence has shown [15]) rises but slightly after a dose of sugar, yet as age advances the curve tends to approach the diabetic type in that the rise becomes somewhat higher and the fall more prolonged The curve from the older subjects has a slightly elevated fasting level, the rise in blood-sugar is slower and more prolonged, the maximum concentration attained is higher, and the fall of the curve more gradual than in youth

These features are demonstrated also in cases of *obesity*, an inability to deal with excess of carbohydrate being a characteristic of the majority of obese subjects In a small proportion of cases of obesity, however, the blood-sugar curve suggests an increased rather than a decreased carbohydrate tolerance It would seem probable that in the early stages of obesity there is an increase in the carbohydrate tolerance—an increase which, no doubt, partly determines the laying down of fat in the storage reservoirs of the body In later stages, however, owing probably to the excessive and continuous strain on the insulin secreting cells of the body a gradual diminution in carbohydrate tolerance occurs, and should tolerance still further diminish, diabetes is the natural sequel The elderly obese diabetic is a common clinical entity, and the association of obesity and diabetes has long been known. The conclusion may be drawn that both in obesity of long standing and in old age the body, presumably through deficiency of the islet cells, is less able to deal so effectively as hitherto with excess of carbohydrate.

(f) *Curves obtained with Glucose and Lævulose*

MacLean [5] has shown that all the ordinary sugars—glucose, maltose, galactose, and lactose—give definite sugar curves after ingestion, curves which closely resemble that obtained with cane sugar, though he finds that lactose gives a slow and rather prolonged rise Lævulose, however, when given in moderate doses, produces no appreciable rise in the blood-sugar concentration in health Lævulose appears to be normally dealt with in the liver, and should this organ be deficient either as a result of diabetes, toxæmia, or gross disease, then lævulose will give a blood-sugar curve very much the same as that obtained with cane sugar

On account of this lack of effect on the blood-sugar concentration in health lævulose has come to be used as a test for hepatic efficiency.

Diurnal Variations in Blood-sugar

(a) *Method*

Throughout a day of 15 hours, in which the subjects of the experiment adhered as closely as possible to their normal existence, blood and urine specimens were collected hourly for sugar estimation At breakfast a certain proportion of carbohydrate, protein, and fat was taken, at lunch half the quantity of carbohydrate was given, but the same amount of protein and fat as at breakfast, at tea a third of the quantity of carbohydrate, protein, and fat as at lunch, while at dinner were taken the same quantities of the essential foodstuffs as at breakfast Meals were served to each individual at about the same time, and were eaten as nearly as possible at the same rate

(b) *Variations in Healthy Persons on Ordinary Diet*

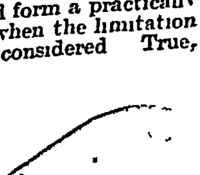
The findings obtained in two *normal subjects* on a diet of about 2770 calories made up of 350 g of carbohydrate, 100 g of protein, and 100 g of fat (a normal one for an ordinary workman doing an "eight hours' day") may be given as an illustration Breakfast (C, 132 g, P, 30 g, F 30 g) taken between 8 30 and 8 50 A M. produced a rise in the blood-sugar concentration of both subjects, but more especially in one whose blood sugar reached the normal renal threshold without producing, however, any glycosuria By 10 A M the blood-sugar had fallen again in both subjects and remained fairly steady until lunch (C, 66 g, P 30 g; F, 30 g) which was taken between 1 20 and 1 40 P M Curiously enough, this meal failed to produce any rise in the blood-sugar in either subject, probably owing to the fact that the carbohydrate was largely given in the form of starch, which is somewhat slowly digested, and hence produces no sudden flooding of the blood stream with the products of carbohydrate hydrolysis During the afternoon the blood-sugar tended to fall in both subjects, but tea (C, 22 g; P, 10 g, F, 10 g) taken between 4 20 and 4 40 P M. produced a substantial rise, despite the small carbohydrate intake, and in both subjects the maximum concentration of blood-sugar was attained about 6 P M Thereafter there was a sudden fall, and then another rise after the evening meal (C, 131 g P, 30 g; F, 30 g) which was taken between 7 30 and 8 P M. Finally, in both subjects the blood-sugar concentration had fallen to normal by 10 P M—that is, two hours after the completion of the evening meal All the urine specimens from these subjects (who were aged 35 and 41 years) were sugar-free

The rise in blood-sugar concentration which occurred in the above subjects towards the late afternoon has been a constant finding both in the normal and diabetic individuals in this series of experiments The causation of this is not clear It can hardly be ascribed to the carbohydrate intake at the afternoon meal, since this amounted—in the diabetic diet—to less than 4 g It is probable that about this time of the day there is a mobilisation of the glycogen reserves of the body with a consequent increase in the amount of circulating glucose, though the possibility of this rise being due to the gradual production of sugar derived from protein metabolism must also be considered

(c) *Variations in Healthy Persons and Diabetics on Diabetic Diet*

The blood-sugar variations which occur throughout the day in *health* are seen also in *diabetes*, but in this condition they are exaggerated In Fig 5 the blood-sugar variations of a *young diabetic* aged 21 are compared with those of a healthy subject of 24 years Both individuals received a diet of approximately 2750 calories, containing about 55 g of carbohydrate, 135 g of protein, and 210 g of fat As in the previous experiment, the same quantities of carbohydrate, protein, and fat were given at breakfast and at dinner, half the amount of carbohydrate, but the same quantities of protein and fat as at breakfast and dinner, were taken at lunch, and a third of these latter amounts of the essential foodstuffs were given at tea

In health both protein and fat produce little or no effect on the blood-sugar, indeed, after protein ingestion "the production of sugar is apparently so gradual that no immediate difference in blood-sugar can be obtained as the result of protein feeding, even in advanced diabetes" (MacLean) It is not surprising therefore, that the blood-sugar concentration of the normal subject (dotted line) should form a practically straight line throughout the day when the limitation of the carbohydrate intake is considered True,



and some idea of the capacity of the kidney for water excretion may thus be obtained This diuresis, however, does not appear to interfere in any way with the final concentration figure the mean of the urinary chloride concentrations during the third hour being identical with that obtained after sodium chloride

Twenty normal individuals were subsequently tested with a dose of 4 g of potassium chloride and 200 c cm of water, the urine being collected hourly for three hours No restrictions were placed on the previous intake of food or drink, the test being started two hours after a self-chosen breakfast The initial concentrations of chloride in the urine, before the test was given, varied from 0 1 to 0 89 per cent, and did not appear to exercise any appreciable influence on the final figures obtained The average concentration of chloride contained during the course of test was 0 915 per cent, with an extreme range of 0 72 to 1 07 per cent In only two cases did the maximum concentration, which was usually attained during the third hour, fall below 0 80 per cent (0 72, 0 79) The average plasma chloride content 90 minutes after administering the dose was 0 376 per cent, with a range of 0 369 to 0 384

It would seem, then, that in normal individuals a comparatively small dose of chloride will in the great majority of healthy individuals lead to the excretion of a urine containing more than 0 8 per cent Cl, and that this level is attained with sufficient constancy to serve as a basis for testing the ability of the kidney for concentrating this radicle Such variations as occur are of the order usually met with in functional tests, and may probably be attributed in part to individual peculiarities of the renal tissue, and in part to the impossibility of exactly reproducing the stimulus to which the organ is subjected

Chloride Concentration in Chronic Interstitial Nephritis

Turning now to cases of renal disease, and taking in the first place patients suffering from chronic interstitial nephritis, we should, of course, expect such patients to show a loss of concentrating capacity for chlorides when examined by the method detailed above Actually the capacity of such kidneys for concentrating chlorides is found to be grossly impaired, and in the severer types of the disease a high grade of fixity of concentration is noted Thus in a patient whose maximal concentration, as tested by the urea-concentration test, amounted to 0 75 only, the concentration of chloride in the urine during the three hours after the administration of 4 g KCl were 0 20, 0 22, and 0 19 per cent, the concentration of the urinary chloride before administration of the salt being 0 20 Taken as a whole, the impairment of the capacity of concentrating chloride in these patients runs closely parallel to the loss of the urea-concentrating power It is remarkable that in these cases the plasma chloride may remain at a normal level even though definite nitrogenous retention is present, in a small series the figure during the second hour of the test averaged 0 375, the highest level attained being 0 404 The absence of hyperchloræmia is not apparently accounted for by retention of water in equivalent amounts to the retained salt, since these patients showed no œdema Veil has, indeed, noticed an excess of chloride in the blood of interstitial nephritis after heavy salt ingestion, and Mayrs has observed a definite hyperchloræmia after doses of 8 and 12 g of NaCl The fact, however, remains that with apparently equal impairment of the capacities for concentrating urea and chloride, gross accumulations of the former are found in the blood, while the latter remains at a relatively constant level Mayrs suggests that the normal plasma chloride in nephritis patients under hospital treatment must be largely due to a restricted diet It may be noted, however, that there is some evidence that "dry" retention of chloride may occur, and that depôts for chloride storage exist in the body The plasma chloride may in advanced cases of interstitial nephritis fall to a very low level, but such hypochloræmia has invariably, in my own experience, been the result of uræmic vomiting with consequent chloride loss, and I see no reason to assume with Veil that it is indication of a profound disturbance of chloride interchange between blood and tissue fluids

From the point of view of chloride excretion, patients showing œdema are of greater interest Thirteen cases of this type were available for examination, and may be divided into two well-defined groups

The first group comprises three cases showing all the characteristics of well-developed chronic parenchymatous nephritis—gross œdema, effusion into the serous cavities, and high grade albuminuria and oliguria The maximum concentrations to the urea-concentration test were 4 9 per cent, 2 2 per cent, and 1 2 per cent, the last patient alone showing definite impairment of nitrogenous excretion In startling contrast to these figures are the results of the chloride-concentration test, which was performed in all nine times on these three patients A typical response may be cited

	Cl per cent	Urine passed	Cl grammes
First hour	0 015	10 5 c cm	0 0015
Second hour	0 017	6 5 c cm	0 0016
Third hour	0 005	7 0 c cm	0 0010

As will be seen, the amounts of chloride passed and the concentrations attained are entirely negligible, though on the following day this patient gave a response of 4 95 per cent to the urea-concentration test At first sight, then it would seem that a complete dissociation of the capacities for concentrating urea and chlorides is present An examination of the plasma chloride, however, suggests that another explanation is possible The plasma chloride in this particular patient was at a level of 0 352 per cent during the second hour of the test while the average figure for the series was 0 349 per cent Eight samples of ascitic or œdema fluid were obtained from these patients and showed an average chloride content of 0 405 per cent (range 0 385–0 427) If we admit that a threshold figure of plasma chloride exists below which the kidney practically ceases to excrete the radicle, another interpretation of the seemingly complete inability to excrete chloride suggests itself The level of plasma chloride in these patients, even after a dose of salts, approximates that usually given for the renal chloride threshold, while the œdema fluid shows a much higher chloride content than the blood It would seem that the disappearance of chlorides from the urine of these patients is the result of the impoverishment of the blood in chlorides and their accumulation in the tissue fluids rather than of a gross renal functional defect In the only patient in whom an improvement occurred, it was noted that simultaneously with the disappearance of the œdema the plasma chloride rose to a normal figure (0 378), while at the same time the response to a chloride-concentration test rose from 0 015 to 0 63 per cent In spite of this striking improvement in the urinary chloride concentration, a very high grade of albuminuria persisted and the centrifuged deposit still showed numerous tube casts From this point of view the renal condition showed no such rapid improvement as one frequently sees in an acute glomerulo-nephritis with onset of diuresis and subsidence of the œdema The direct evidence obtainable from urinary examination, therefore, does not suggest that the sudden improvement in chloride concentration is the result of a corresponding improvement of the pathological condition of the kidney It is unfortunate that the cases of typical parenchymatous nephritis which came under examination were so few in number, but the facts observed are suggestive It would seem that elevations of blood-sugar concentration can be controlled by insulin injected at a suitable interval of time—about 30 minutes—before the chief meals of the day.

In conclusion, I wish to express my thanks to those members of the staff of Ruthin Castle who allowed themselves to be the subject of experiment, to my colleagues A. J Leigh, J S Jeffery, and T J Dobie for the numerous blood-sugar estimations, and lastly to Dr Spriggs for his kindly help and advice

ON THE CAPACITY OF THE KIDNEY FOR CONCENTRATING CHLORIDE.

BY O L V DE WESSELOW, M B OXF,
F R C P LOND,
PHYSICIAN WITH CHARGE OF OUT-PATIENTS, AND CHEMICAL PATHOLOGIST, ST THOMAS'S HOSPITAL, LONDON

IN recent work on the subject of the excretory capacity of the kidneys attention has been focused to a large extent on the excretion of the nitrogenous waste bodies, and the question of chloride excretion has excited but little interest This comparative neglect is probably in part due to the amount of labour involved in prolonged chloride balance experiments, and the difficulty of carrying out such experiments on sick patients, and in part due to the feeling that the whole question has been settled by the classical work of Widal The views of this author as to the part played by defective renal excretion of chlorides and consecutive water retention in the production of renal œdema have, however, been gradually losing favour One may, for instance, cite the findings of Volhard and Fahr, who discovered that during the initial stages of "renal" œdema the blood, far from showing the expected dilution, is actually concentrated, as evidence of the obvious difficulty of accepting a primary renal origin of the dropsical condition The use of a salt-free diet in the treatment of renal œdema has also not fulfilled our original expectations The pendulum has, in fact, swung in the opposite direction, and the rôle played by the chlorides in the production of renal œdema is regarded by many authors as altogether subservient to that of the proteins of the plasma It is widely believed that loss of protein through the damaged renal epithelium leads to such a diminution in the plasma protein content and so alters the osmotic relationships between plasma and tissue fluids that water leaves the blood and enters the tissues On this assumption variations in the concentration and quality of the proteins determine the distribution of water in the organism Loeb, however, in his review of the œdema question, concludes that sodium chloride rather than protein plays the predominant part in controlling water distribution in the body If this is so, the question of the capacity of the kidney for chloride excretion still retains its importance in our investigations of renal dropsy The following experiments were put through with a view to studying this aspect of renal function

Renal Capacity for Chloride Excretion

It is hardly necessary to stress the inconclusive nature, as far as renal function is concerned, of the balance experiments on which the chloride retention theory of œdema rests It is well known that if the blood content in chloride falls below a certain level, excretion of chloride by the kidney ceases Instances of such disappearance of chloride from the urine, not due to any functional defect of the kidney but to impoverishment of the blood in salt are seen in lobar pneumonia and in war gas-poisoning, in both of which conditions exudation of chloride-rich material into the lung leads to pronounced fall in the chloride content of the blood The apparent chloride retention in such cases is in reality proof of an intact regulatory function of the kidney rather than an excretory defect

Relatively few workers have attempted to test the renal capacity for chloride excretion directly Ambard, indeed, has devised a method of estimating the renal threshold for chlorides, based on his ureo-secretory constant, defects in chloride excretion are estimated by the rise in the renal threshold for this salt, the threshold itself being determined indirectly The method is however, somewhat elaborate for routine clinical use, and entails assumptions as to the identity of the secretory constant for various bodies, which may well be called in question Ambard also noted that in man the concentration of Cl in the urine may reach a figure of 1 to 1 3 per cent The question of maximal chloride concentration has also been studied by Volhard, who states that the highest figure that can be attained by the healthy human kidney is 1 per cent Adolph and Haldane, giving large doses of salt, found concentrations of 1 to 1 2 per cent Cl and Addis in morning urines found figures of 0 82 to 1 35 There is thus a general agreement that in health the urinary Cl may reach a figure of approximately 1 per cent, the highest concentration noted being 1 35 In many of these experiments large quantities of chloride were administered and in addition the water-supply was limited

Chloride Concentration in the Healthy

Such conditions cannot, of course be reproduced in the sick patient, but in a series of experiments on a healthy individual I was surprised to find that a urinary chloride concentration not far below the maximum could be elicited by administering comparatively small quantities of salt The highest concentration attained by this kidney was 1 03 per cent, after 17 g NaCl and water deprivation, a nauseating and unpleasant experience On the other hand, in six experiments with doses of 4 g NaCl or KCl, taken in cachets and washed down with 200 c cm of water, an average concentration of 0 905 Cl was reached, the maximum figure being usually attained in the third hour of the test The range of the highest concentrations in these experiments was from 0 84 to 0 94 per cent The plasma chloride was estimated during the second hour of the test with a view to establishing a constant relationship between plasma and urinary chloride The figure obtained varied between 0 369 and 0 380, but no such constraint relationship could be found A larger diuresis followed the potassium salt than the sodium, potassium salts being active diuretics, above the edge of the pubic bone On separating the anterior surface of the organ from the overlying structures pus became apparent On further separation this was found to be coming from a wound in the long axis of the uterus extending from the upper pole into the lower segment The edges of this wound were easily separable, and showed much suppuration, lying in the wound was a long catgut ligature This was removed, placed at once in a sterile test tube, and kept for culture Portions of the suppurating edges of the uterine wound were also taken and kept for culture The interior of the uterus showed no collection of pus The uterine adnexa showed no abnormality Kidneys Very congested but otherwise normal Spleen, soft and friable, but not greatly enlarged Other organs Nothing abnormal

Bacteriological Examinations—Films of the pus from the uterine wound showed Gram-positive cocci and Gram-negative bacilli only Aerobic plate cultures gave a pure growth of *Staphylococcus aureus* Anaerobic cultures in bullock's heart broth were made as follows (*a*) Of the catgut ligature referred to above, (*b*) and (*c*) of portions of suppurating tissue from the edges of the uterine wound All cultures were incubated for 48 hours

On examination by film culture (*a*) showed numerous morphological *B tetani* One of the cultures from the uterine tissue showed the same organism in smaller numbers the third culture showed no tetaniform organisms All three cultures showed various other types of anaerobic organisms, but no other end-sporing types

Animal Experiments—(1) March 12th, 1926 Two guinea-pigs used at 11 30 A M Guinea-pig 1 (control) received intraperitoneally 5 c cm mixed anti-gas gangrene serum and 500 units antitetanic serum Guinea-pig 2 received by same route 5 c cm anti-gas gangrene serum only 5 30 P M. Both guinea-pigs were inoculated in the right thigh with 1 c cm of culture (*a*) This had stood overnight in the ice chest Six hours previous to inoculation 2 c cm of the culture were mixed with 10 c cm of anti-gas gangrene serum Each of the guinea-pigs received 6 c cm of this mixture Both guinea-pigs were kept under observation for two weeks, but neither showed any ill-effects

For various reasons work on the cultures at this stage had to be suspended until the middle of April. As it was thought that the nature of the medium might have had something to do with the failure to produce tetanus in guinea-pigs in the first experiment it was decided to perform a second experiment, using an ascitic broth culture Subcultures were therefore made from the original meat broth culture into ascitic broth and incubated anaerobically. After three days' incubation these cultures showed numerous tetaniform bacilli It was also considered possible that there might be traces of tetanus antitoxin in the anti-gas gangrene serum used to barrage against the gas forming anaerobes, and it was decided to omit the use of this serum

Experiment (2)—A third subculture into ascitic broth incubated for three days was used Guinea-pig 1 (control) received 500 units of antitetanic serum intraperitoneally. It was then inoculated with 1 c cm. of the culture in the right thigh, the injection of the culture being immediately followed by 1000 units of antitetanic serum Guinea-pig 2 received 1 c cm of the culture alone Neither of the guinea-pigs showed any ill-effects

By this time considerable doubt was being entertained as to the nature of the tetaniform organism. It was decided, however, to perform one more experiment, taking advantage of the known catalytic effect of the presence of silica along with the organisms For this purpose a 48 hours subculture into meat broth from the ascitic broth was used

Experiment (3)—April 24th, 1926 A quantity of ordinary sand was heated in a crucible over a bunsen flame for one hour At the conclusion of this heating it was poured into a test tube full of sterile saline, and allowed to stand for a few minutes The coarser particles settled to the bottom, leaving the finer particles in suspension Guinea-pig 1 (control) received 1 c cm of this suspension into the right thigh Guinea-pig 2 received 1 c cm of the sand suspension followed by 1 c cm of the culture

At 11 A.M. on April 25th guinea-pig 2 showed an intense and very characteristic spasm of the injected leg It was not seen again until 5 P M It was then in a condition of intense general spasm. All four legs were in extension and the whole body bent backwards and to the right so that the nose almost touched the thighs So severe was the condition that the animal was at once chloroformed At post mortem the site of inoculation showed œdema, but no pus formation. Films showed no organisms and only a few pus cells Cultures from the œdema fluid incubated anaerobically for three days showed numbers of *B tetani*

Discussion

The point of greatest interest is the extreme difficulty presented by the diagnosis during life Matters were very much complicated by the fact that the patient was a neurotic woman, and that she had before the operation harboured a dread of tetanus When she developed a risus sardonicus after the operation it was inevitable that suspicion of a neurosis should be aroused, and this was strengthened by the absence of other well-marked symptoms of tetanus during the ensuing days up to the time of death The spasmodic attacks appeared to be entirely confined to the muscles of the face and throat, and were quite different from the spasms seen in an ordinary case of wound tetanus In fact, almost the only characteristic sign of tetanus which the patient presented, apart from a risus sardonicus, was cessation of life Why death occurred it is difficult to say The spasms did not last long enough to cause death from asphyxia, and there was no exhaustion such as is seen in a well-developed case of tetanus It would appear that the tetanus toxin has potentialities for damage beyond its mere power of producing spasm, to an extent not usually realised

The fact that on culturing portions of the uterine tissue, and also of the catgut used in suturing that organ, the tetanus bacilli were obtained in by far the greatest numbers from the catgut would appear to implicate the ligature as the source of the infection Two other samples of catgut from the same lot, but not from the same phial, were examined anaerobically, but neither gave any growth

From the bacteriological standpoint it is interesting to note the very powerful effect of the addition of a little sand to the cultures of the tetanus bacillus

Summary.

1 A fatal case of tetanus following upon Cæsarean section is described

2 The catgut used in suturing the uterus is implicated as the source of the infection

3 The diagnosis was rendered difficult by the ill-marked and mild nature of the symptoms and the fact that the patient was known to harbour a fear of tetanus

The sole share of the author in this case was the performance of the post-mortem examination and the bacteriological procedures, and his thanks are due to the surgeon in charge of the case for his kindness in providing full clinical details

Clinical and Laboratory Notes.

FULMINANT CASE OF ACUTE POLIOMYELITIS OF BULBAR TYPE.

BY F C COLLINSON, M R C S ENG, J P,
SENIOR SURGEON TO THE ROTHERHAM HOSPITAL, DEPUTY CORONER FOR ROTHERHAM

THE following case presents sufficient features of interest to make it worth recording

A girl, aged 11½, had been in her usual health until about midnight on June 2nd–3rd, when she called out, "Mother, I'm sick" She vomited once, and for the rest of the night was restless and a little delirious, only sleeping at intervals Next day she got up as usual, but did not go to school Nothing definite was noticed She went to bed in the usual way that night, and next morning, June 5th, she got up about 10 30 o'clock and played about with her brother. About 1 30 P M the child was looking ill, and was sent to lie down. At 6 30 P M (that is about 42 hours after the previous vomiting) she vomited again, bringing up some frothy white material. She now complained for the first time of some difficulty in swallowing but it was not pronounced From this time onwards the difficulty of swallowing increased and by 10 o'clock that night she could not swallow at all Even a little milk put in the mouth was churned about, and eventually put out

Condition on Examination—At 11 30 A M on June 6th, when I was called to see her, the temperature was 103° F, pulse 120, respiration 20 She was frothing at the lips, restless, and in a state of great alarm There was no squint or inequality of the pupils When water was given to her she appeared to roll it round in her mouth, and the froth about her lips increased She kept pushing the head forwards, and the larynx rose up, but no liquid seemed to in these patients the kidney probably lacks opportunity rather than capacity for excreting chlorides that the diversion of chloride and probably water from the blood to the tissue spaces leads to the almost total disappearance of chloride from the urine and to the extreme oliguria, and that, given the opportunity, the kidney still possesses a very fair capacity for chloride concentration The œdema is, in fact, rather of extrarenal than of renal origin and results from a general alteration in the capillary permeability of the body It is probable that the seeming dissociation of the capacities of the kidney for urea and chloride concentration is apparent rather than real, and it is questionable whether these cases form an exception to the general rule that the various concentrating capacities of the kidney are closely interrelated

Chloride Concentration in Cases with other Renal Lesions and Dropsy

The second group of œdematous cases examined, ten in number, present a striking contrast to the first In all a renal lesion was present, as evidenced by albuminuria and casts, and no other cause for the œdema could be found The dropsy was, however, less well developed than in the parenchymatous nephritis, and no appreciable effusion into the serous sacs was detected in any of these patients The group included such conditions as pre-eclampsia and eclampsia, acute glomerulo-nephritis, chronic nephritis, complicated by pregnancy, persistent œdema of the legs with albuminuria after acute nephritis and exacerbations of chronic nephritis The response to the chloride-concentration test in these cases was relatively good and in two cases reached a figure in excess of 0 80 per cent Where impairment of chloride-concentration was present, a correlated and roughly equivalent impairment of the power of concentrating urea was noted No such extreme failure of chloride-concentrating power was noted as appears to be the rule in chronic parenchymatous nephritis, the lower range of chloride concentration obtained was in the neighbourhood of 0 15 to 0 20 per cent —that is, about at the level frequently seen in chronic interstitial nephritis The average content of plasma chloride during the test was 0 386 per cent varying from 0 367 to 0 404; the plasma chloride is thus slightly in excess of the normal figure No samples of the tissue fluids were obtained It does not appear that the œdema present in these cases could be attributed to loss of the capacity of the kidney for chloride concentration, since as low or lower chloride concentrations may occur in interstitial nephritis free from any trace of dropsy The group as a whole showed, however, a somewhat impaired diuretic response to the potassium salt, as compared with the normals and with other nephritics free from dropsy

Conclusions

1. A simple method is suggested for testing the capacity of the kidney for concentrating chlorides 2 The capacity of the kidney for chloride concentration appears to run parallel with its power of concentrating urea, both functions being affected in disease to an approximately similar degree 3 An apparent dissociation of the two functions is seen in cases of parenchymatous nephritis with gross anasarca, but it would seem that this is merely the result of impoverishment of the blood in chloride

A CASE OF
POST-OPERATIVE TETANUS WITH IDENTIFICATION OF THE ORGANISM

BY S C DYKE, D M OXF, M R C P LOND,
CONSULTING PATHOLOGIST, WOLVERHAMPTON AND STAFFORDSHIRE HOSPITAL.

THE rarity of tetanus following operation with present-day aseptic technique and the fact that in this instance the diagnosis, which would have been doubtful on clinical grounds alone, was proved by the identification of the organism form the justification for the publication of the following case

Clinical History

Patient was a married woman, aged 38, of rather neurotic temperament She had had one previous pregnancy which had ended in craniotomy on account of "contracted pelvis" When she became pregnant a second time it was therefore decided that delivery should be by Cæsarean section Labour commenced at 10 P M on Feb 16th, 1926 No examinations were made, labour was allowed to proceed for one and a half hours and the section was then performed, resulting in the delivery of a healthy male child The operation presented no unusual difficulties, the uterine wound was closed with divided catgut sutures and a continuous stitch of the same material, the wound in the abdominal wall was closed in the usual way For two weeks after the operation all went well The lochia were entirely normal, and the wound in the abdominal wall healed cleanly Involution of the uterus took place at a normal rate Preparations were in train for the removal of the patient and her baby to her own home, when on March 4th she complained that her tongue felt swollen and her jaws stiff On the morning of the following day the patient presented a risus sardonicus, and there was some trismus and retraction of the neck There was no stiffness of the muscles of the trunk or limbs, the reflexes were not increased, and there was no indication of spasm other than that of the muscles of the face and neck On the strength of such symptoms as existed the patient was given 100,000 units of antitetanic serum, 20,000 units into the spinal theca, and the remainder intramuscularly The temperature in the evening rose to 101° F

On March 5th the patient appeared to be better The retraction of the neck had disappeared, the trunk and limb muscles remained unaffected, and the nurse stated that during sleep the patient's mouth fell open In the absence of any very definite symptoms of tetanus, and in view of the patient's neurotic temperament, very considerable doubt began to be felt as to whether there was any tetanic infection at all This doubt was much strengthened when interrogation of the patient's husband elicited the extraordinary fact that the patient had dreaded getting tetanus after the operation, and had even approached her own medical practitioner with a view to getting him to give her a prophylactic dose of antitetanic serum It appeared that this dread on the part of the patient arose from the fact that in her youth she had seen a case of tetanus in a farm hand and was therefore more or less familiar with the symptoms During the afternoon of this day the patient developed a series of spasmodic attacks in the course of which she clenched her teeth, held her breath, and became cyanosed The trunk and limb muscles remained unaffected, during some of the attacks there was incontinence of urine and fæces The temperature varied between 100° and 101°.

On March 7th the patient was quiet and fairly free from the spasmodic attacks until the middle of the afternoon By this time a definite decision had been reached that the symptoms were neurotic in nature, and arrangements were being made for the transfer of the patient from the surgical ward in which she had been treated, when she suddenly had another spasmodic attack, and conclusively confuted the diagnosis of a neurosis by dying a few minutes after its apparent subsidence

Autopsy

Post-mortem Examination —March 9th 1926 The body was that of a somewhat emaciated female, breasts full, on the abdomen in the mid-line was a completely healed surgical wound Brain Vessels very congested, no other signs of abnormality Thorax Lungs normal, some froth in the trachea, early atheroma of the aorta, in particular about the mouths of the vessels Heart Nothing abnormal Abdomen The wound in the abdomen showed no collections of pus, healing of all layers of the wall had occurred, and there were no adhesions between the deep aspect of the scar and the underlying viscera The uterus was contracted down so that its upper pole just reached

At 5 A.M. the plugging was removed from the vagina and a quarter of an hour later she delivered herself of a still-born fœtus The placenta and membranes rapidly followed, together with some retroplacental blood-clot At one edge of the placenta the area over the os could be easily determined, and at the opposite side there was retroplacental blood-clot At 6 A.M she was sweating profusely and the blood pressure had dropped to 116 mm Hg Consciousness was returning No urine had been passed During the day. however she gradually improved, though she was drowsy to a degree approaching coma Her face became more puffy and the œdema of the legs was more marked Sweating was maintained by a further injection of pilocarpine gr ⅙

On Nov 1st she was still improving but no urine was passed In the evening, at 7 o'clock, a catheter was passed and 7 oz. of urine drawn off This contained a large amount of albumin and many casts, blood cells, and pus The urea was 0 7 and the chlorides 0 27 per cent As by the history she had not passed urine since the evening before admission she had had complete suppression for 72 hours

On Nov 2nd 13 oz. were passed naturally and on the 3rd 65 oz. She was now taking a large amount of fluids by the mouth, and on Nov 4th she passed 140 oz.

She made an uninterrupted recovery and was discharged on Nov 26th feeling quite well, with the urine free from albumin.

The administration of ergot intramuscularly at three-hourly intervals undoubtedly stimulated the uterus to expel its contents and so made recovery possible

I am indebted to Mr L C Rivett for permission to publish this case.

A CASE OF ADENOMA OF THE JEJUNUM CAUSING INTUSSUSCEPTION

BY R CHARLES B MAUNSELL, F R.C S IREL ,
PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND , SURGEON TO MERCER S HOSPITAL, DUBLIN ,
PRESIDENT OF THE SURGICAL SECTION, ROYAL ACADEMY OF MEDICINE IN IRELAND

THE following case is of interest on account of its rarity and also as an example of the impossibility of making a diagnosis in some abdominal conditions without the aid of an exploratory operation

E. M., female aged 26, was sent to me on March 31st, 1926 She had been complaining of abdominal pain and vomiting for two years and, in spite of prolonged hospital treatment, the symptoms had become worse. The pain was situated in the upper abdomen and also in the back at the same level, and sometimes if she turned on her right side, she felt a " gushing " starting from her back and travelling around the left side The ingestion of solids or fluids increased her pain, and fluids gave her a feeling of great distension. When she vomited the pain became very intense for some minutes but then died away, except from her back where it was almost continuous She often put her fingers down her throat in order to hasten the emptying of her stomach. The vomited material always contained bile, but she never noticed any blood. She stated that on many occasions her motions were black in colour and sometimes she passed red blood For the past few months she had lost flesh and had become weak and suffered from lightness in the head." Her bowels have been constipated and she frequently took aperients

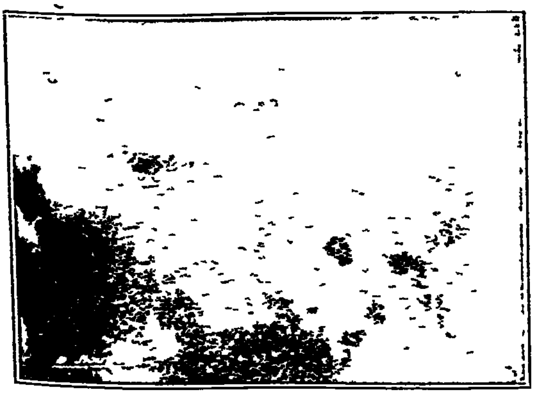

FIG 1 —Six-hour retention of barium meal in third stage of duodenum

Upon examination she was fairly nourished, but was extremely anæmic Hb 30 per cent W.B C. 5466 per c mm. R B C 4,820 000 She remained in hospital for five weeks before operation, and during that time her pulse temperature and urine remained normal. There was at no time blackness of the motions nor was any red blood passed, but " occult blood " was demonstrated in the fæces Palpation and percussion revealed nothing except slight tenderness in the upper abdomen.

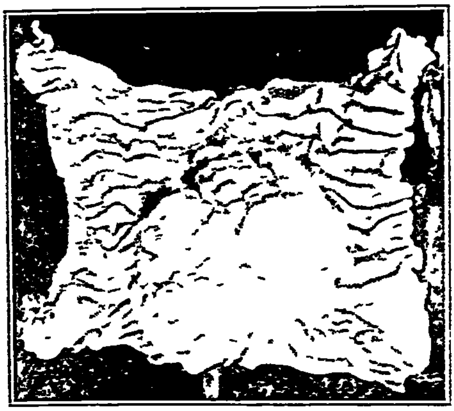

FIG 2 —Sessile adenoma of the jejunum

A provisional diagnosis was made of gastric ulcer or duodenal ileus, or a combination of both. and she was referred to the X ray department The following extracts from the radiologist's report are of interest . " Stomach—normal in position, size, shape, and tone, and the evacuation of its contents was fairly free There was some tenderness over the pylorus and duodenum. There was marked delay in the third part of the duodenum, and in six hours when the stomach had emptied completely there was a residue still present in the duodenum (Fig 1) The diagnosis is uncertain. but some mechanical obstruction involving the third part of the duodenum is suggested. It is probable that the second and third parts are considerably dilated The obstruction may be due to pressure of the mesenteric artery, but there is no pronounced visceroptosis " Upon reading this report we felt quite confident that the provisional diagnosis was correct and on May 7th I opened the abdomen.

Operation —The stomach and upper portions of the duodenum were normal. When the transverse colon and mesocolon were turned up a very curious condition was seen. Intestine several inches in circumference appeared to emerge from a depression in the transverse mesocolon at the point which should have been the site of the duodenal jejunal flexure This enlarged intestine could be traced down for 9 or 10 inches before it tapered into normal jejunum. Examination showed that it was an intussusception. the neck of which in its efforts to swallow the duodenum. had formed a depression in the transverse mesocolon. The distal portion of the intussusception was withdrawn from the abdomen and by careful manipulation the intussusception was squeezed back. A soft mass could then be felt in the lumen of the intestine it appeared to be about the size of a golf ball, to be sessile, and situated about 8 inches from the duodeno-jejunal flexure About 3 inches of the intestine was resected and continuity re-established by end-to-end anastomosis No other tumour was felt in the abdomen. The pathologist reports that the tumour is an adenoma (Fig 2) The patient has had no symptoms since the operation and is rapidly regaining her normal strength and complexion.

I had only once previously met with an adenoma of the jejunum, and it also caused an intussusception. I operated upon the patient some 20 years ago and. although the notes and specimen have been mislaid. I have a very distinct recollection of the case

The patient was a young man aged 25 years who suffered periodically from intense abdominal pain sometimes accompanied by vomiting Many diagnoses had been made including hysteria and malingering but luckily the house surgeon was present during one of the attacks and he thought that he could feel a tumour in the upper abdomen. When I examined the patient next morning this tumour could not be felt I opened the abdomen and found evidence of a recently reduced intussusception 2 feet below the duodeno-jejunal flexure and I removed a pedunculated adenoma from the lumen of the intestine

In conclusion I wish to thank my colleagues Dr. Leonard Abrahamson for medical consultations Dr T G Hardman for X rays and Dr J. Lar for pathological reports go down the œsophagus It was not possible to make a complete examination at the moment, but there was nothing abnormal to be seen in the pharynx Before I could make a second visit death had occurred The parents say that about 1 30 P M —that is, two hours after I saw her—she became very excited, went stiff, and clutched at the bed-rail, struggling up to the time of her death She did not go blue Death occurred at 2 P M on June 6th Permission for autopsy was not obtained, but the throat was carefully examined and nothing abnormal found

Commentary

Here we have an acute illness fatal in 62 hours There is an onset with vomiting, and general toxic symptoms, restlessness, malaise, delirium, and after an interval of about 40 hours the localising symptoms show themselves, in this case limited to dysphagia, suggesting serious damage to some part of the lower medullary region At the same time there was evidence of general infection from the temperature and pulse There was no history of any injury, no drugs of any kind had been taken, and the differential diagnosis seems to lie between two infections, each of neurotropic type, acute poliomyelitis and epidemic encephalitis In favour of acute poliomyelitis is the age of the patient, the onset with vague febrile symptoms a few hours before the appearance of local paralysis, the extreme severity of this latter, and its limited extent It is impossible on the data to exclude epidemic encephalitis, indeed, cases of a somewhat similar type have been recorded from time to time, and referred to as "hydrophobia-without-the-dog" Arthur Hall records a case of this kind in a woman in whom hydrophobia was suspected and tracheotomy had to be performed[1] Cases have also been described by Denyer and Morley in a young man,[2] Kahn, Barbier and Bertrand[3] in a woman of 52, and Sarkies[4] in a medical man These cases, however, differed in certain respects from my case In all of them there were violent spasms of the larynx, which were increased by attempts to swallow, whilst in my case the trouble appeared to be limited to the loss of swallowing It is possible, however, that after I saw her such spasm of the larynx may have occurred, and indeed some further extension of the trouble must have taken place to cause her sudden death

Apart from these rarer bulbar cases seen in epidemic encephalitis, dysphagia of a temporary kind is by no means uncommon as an early symptom in this disease It is, however, usually accompanied by other evidences of cranial nerve involvement, ocular, facial or tongue palsies Moreover, it is unusual for these early cranial nerve palsies of epidemic encephalitis to be the cause of death, or for death to occur during their existence. It is a somewhat surprising fact that the toxin of epidemic encephalitis seems to flit about the bulb causing a palsy on this side one day, a palsy on the other side the next, and yet seems to avoid the vital centres It is rare for death to occur at this period, when bulbar-pontine palsies are occurring Further, as is well known, these early cranial nerve palsies are rarely permanent the damage seems to be less than destructive That acute poliomyelitis may involve the brain stem is well known, and such cases may be rapidly fatal Feiling[5] records a case in a youth of 19 who began to feel ill on Nov 19th 1913, with a peculiar feeling in the throat Two days later he had difficulty in swallowing, and weakness in the left leg The dysphagia became complete, there was pyrexia, and a year later he had an attack of severe dyspnœa and a convulsion, and died a few hours later Definite signs of acute poliomyelitis were found in the central nervous system Feiling's case was published before the question of epidemic encephalitis as a separate entity had arisen, but the clinical account of it does not suggest the latter disease Poole[6] in 1925 recorded two cases of what he termed acute polio-encephalitis Both had dysphagia amongst other bulbar symptoms, and died within a few hours of admission He discusses the diagnosis between Heine-Medin's disease and epidemic encephalitis, without making it very clear as to which way his own opinion leaned Apparently there was no autopsy in either of his cases

It seems on the whole probable that the case which I have recorded was one of acute poliomyelitis (polio-encephalo-myelitis) limited to the bulbar region

A CASE OF COMPLETE SUPPRESSION OF URINE FOR THREE DAYS

By A Leslie Lankester, B A Camb, M R C S Eng,

LATE SENIOR RESIDENT MEDICAL OFFICER, QUEEN CHARLOTTE'S HOSPITAL

The case here related is of interest not only on account of the long period of anuria, but also because of the large amount of pilocarpine which was given before the skin reacted

E S, a primigravida of 41, was attending the antenatal department of Queen Charlotte's Hospital and was under treatment for albuminuria The treatment had been dieting, by the restriction of proteins, and the administration of alkalies and saline purges During the night Oct 29th–30th, she slept badly, and in the early morning there was a small loss of blood from the vagina The patient also had some "giddiness" and some "biliousness" A further loss caused her to come up to the hospital, and she was admitted at 11 A M.

Condition on Admission —The patient was very pale, pulse 64, temperature 95 6° F , ankles slightly œdematous , systolic blood pressure 160 mm Hg She complained of slight epigastric pain and a few specks before the eyes Mentality was perfectly normal and the patient was only worried about herself because of the bleeding The uterus was fairly hard but not specially tender, and normal elasticity was not present Maturity was about 34 weeks There was a steady trickle of blood from the vagina and the edge of the placenta was felt through the cervix A diagnosis of placenta prævia was made and the pallor was thought to be due to loss of blood

She was put to bed, kept warm, and watched The bleeding continued and at 4 P M. it was decided to plug the vagina She was given an anæsthetic, the membranes were ruptured, and the vagina firmly packed with three 6-yard rolls of 6-inch gauze

The patient took the anæsthetic badly the pulse being barely perceptible most of the time, but there was no further loss An injection of 1 c cm of pituitrin was administered and rectal salines were given At 7 P M she was very restless and delirious At 9 P M she was intensely anæmic, the mucous membranes being almost lemon coloured, and the respirations were becoming stertorous She had a curious "barking" cough and frequently vomited a dark-brown fluid

No urine had been voided since admission to the hospital A catheter was passed and the bladder was found to be empty Her condition was so bad that any radical treatment was contraindicated A diagnosis of combined toxæmic accidental hæmorrhage and placenta prævia was made and restorative treatment adopted, the prognosis being regarded as hopeless

The colon was washed out with saline, and an intravenous saline containing sod bicarb gr x ad 1 pint given Hot packs were applied in an effort to get the skin to act, pilocarpine gr ⅙, subcutaneously, and ergotin, 1 c cm, intramuscularly, being injected By 11 P M she was in deep coma, respirations hardly perceptible, the pulse impalpable, and the heart sounds only faintly heard with a stethoscope Oxygen and camphor, gr iii, in oil with strychnine and digitalin hypodermically were given as cardiac stimulants At midnight the pilocarpine, gr ¼, and ergotin, 1 c cm, were repeated There was no change in the condition

Rectal salines were still being administered every hour and were retained, and at 2 A M on Oct 31st she was given a steam vapour bath and the pilocarpine gr ¼, repeated The blood pressure was now 136 mm No moist sounds were heard at the bases of the lungs An hour later, 3 A M, there was some vasodilatation, and a few moist râles in the lungs, indicating that the pilocarpine was acting The vomiting recurred on one occasion, otherwise the patient was in deep coma, but the respirations improved slightly as the skin began to act

By 4 A M the skin was definitely acting and perspiration became visible Her general condition was slightly improved and she appeared to be having definite uterine contractions yet so many cases which started as a hæmorrhagic went on into a chronic nephritis that he thought a classification of acute nephritis was not practicable There were two forms of nephritis in infants under 12 months which Dr. Parsons had not mentioned but which were of great importance In the one there was a febrile illness occurring in a child say 6 months old, this illness simulated a respiratory disorder, and the diagnosis was often bronchopneumonia but there were no chest signs, and the examination of the urine showed a considerable degree of albuminuria and casts. The other form was a syphilitic nephritis, which was characterised by marked œdema. The diagnosis of the latter form was of great importance, because these cases were in his experience universally fatal. With regard to chemical tests he agreed with many of the remarks made but he considered that continued blood-urea observations were of the greatest importance in the prognosis of nephritis As to the remarks made about a protein dietary, he would point out that a milk diet contained a considerable amount of protein; indeed the protein in three pints of milk was equivalent to that contained in half a pound of beef-steak, but possibly there were other constituents of meat associated with the protein which were really more important than protein itself

Dr **Hugh Barber** (Derby) said that 20 years ago cases of acute nephritis which were not due to scarlet fever were regarded as idiopathic, but more recent investigations had demonstrated the importance of focal sepsis in the throat, nose ears, and teeth The cases put down as idiopathic in origin became fewer although with our present want of knowledge such a group was still necessary. There was not any evidence of epidemic nephritis in childhood. He would stress the importance of early diagnosis since some cases of acute nephritis were somewhat insidious in onset and it was possible for a child to be ill several days outside hospital before attention was called to the urine. Of the numerous complications there were two points which appeared to him to be worthy of emphasis First, that pericarditis was fairly common and was insidious in onset, giving rise to little, if any pain Secondly that persistent vomiting might be the only sign of uræmia. Renal efficiency tests were more interesting in prognosis during convalescence but were not sufficiently delicate to help very much although the estimation of the blood-urea was a useful guide to diet in these cases which had progressed to an extreme degree of œdema with much albumin in the urine since in such cases a diet rich in protein gave the best results Judged clinically, the prognosis was severe in proportion to the length of time the acute symptoms were present and a diuresis was the first sign of improvement The chief essential in treatment was absolute rest in bed and keeping the child warm between blankets Mild diuretics might not do any harm, but neither excess of fluid to drink nor drugs of any sort were of much use. Convalescence should proceed very gradually. Children after an attack of acute nephritis should not be allowed to go about with thighs and legs uncovered for there was no doubt that cold disposed towards a relapse when a lesion was or had been present.

Dr **H T. Ashby** (Manchester) wished to draw attention to a line of treatment for chronic nephritis but seldom used at present—namely, decapsulation of the kidney. It was possible that a further trial of this procedure might prove of value, particularly in turning the scale in a case which was doing badly because subsequent to decapsulation a marked diuresis occurred It was doubtful how the results of decapsulation were brought about but three theories had been advanced First that the depriving the kidney of its capsule and then bringing the cortex into contact with perinephritic tissue led to the promotion of new vessels which anastomosed with those of the kidney, and thus provided for the removal of inflammatory exudate and assisted in re-establishing the renal function. Secondly that the effects were due to the relief of tension but as a matter of fact tension was not always present. Thirdly, it had been suggested, and he thought it the correct view, that the mechanism of the production of the diuresis and the disappearance of the œdema was the same as in the process of wet cupping and that direct cupping was done to the kidney itself by decapsulating it If this were true he wondered if simple incision of the kidney would not prove as effective as decapsulation.

The **President** remarked that he had been quite as much interested during the discussion in what had been omitted as in what had been included. Venesection for some centuries had been an almost universal mode of treatment of acute disease, but had gone out during the last generation, yet there could be no doubt that a timely venesection in acute oliguria of adults was of the greatest service and well worth considering in children. Decapsulation of the kidney in acute cases owed possibly its somewhat rare successes to that principle. Renal efficiency tests that morning appeared out of favour, either as a means of diagnosing types or as affording grounds for prognosis: he thought that the standard of such tests had been insufficiently established in children, either in normal health or in those suffering from diseases other than those of the kidney.

Dr **Wilkie Scott** (Nottingham) thought that decapsulation of the kidneys should be done in very acute cases with suppression of urine, and particularly if the case appeared to be an acute attack engrafted upon a chronic nephritis He also stressed the importance of slight, often overlooked, attacks of acute nephritis in infants.

Dr. **N C Capon** (Liverpool) did not like the use of the word "nephrosis,' because if this label were correctly employed it meant that the changes in the kidney were due to degeneration, and not to inflammation; such a condition must be an extremely rare one because in all the hydræmic cases which he had examined there was always evidence of inflammatory changes He thought that it was a mistake to limit the protein in the diet in hydræmic cases, because in them the protein content of the blood was much diminished With regard to Dr Parsons's suggestion that the tonsils should not be removed until the third month, he thought that if these were infected they should be removed at the earliest possible *moment*

Dr **C. W. Vining** (Leeds) emphasised the importance of rest in the treatment and thought that it was most important that hospital accommodation should be available to give these patients prolonged rest.

Dr. **H. Chodak Gregory** (London) commented on the severe constipation occurring in some of these children and had also noticed the association in early infancy of acute nephritis with septic rashes

Dr. **Parsons** in reply, said that he agreed with Dr. Smellie in disliking the application of the term parenchymatous to the exudative group of acute nephritis, but that he had made use of the term because such cases had been labelled parenchymatous for many years and had received the sanction of antiquity As to the term nephrosis, different authorities gave different definitions but he agreed with Dr Capon that there was rarely evidence of degeneration and usually evidence of inflammation. He (the speaker) also agreed that if there was evidence of infection of the tonsils they should be as a rule removed at the earliest possible moment, but he had on rare occasions seen an exacerbation of the kidney condition follow the operation and therefore in his opening remarks he had ' played for safety."

GOITRE IN CHILDHOOD.

A paper on this subject read by Dr C H. **Milligan** (Glossop) gave the point of view of a whole time public health officer. The definition of goitre adopted in his inquiry was a visible enlargement of the thyroid. The incidence varied with age, sex, and locality In a total of 1870 children examined, goitre occurred in 0 9 per cent. of those under 7 years of age, 8 4 per cent. in boys of 13, and 25 9 per cent. in girls of 13

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT NOTTINGHAM

(Continued from p 551)

SECTION OF DISEASES OF CHILDREN.

Wednesday, July 21st.

Dr **Hugh Thursfield**, the President, in opening the business of this Section, referred to the great loss sustained by pædiatricians in the death of Dr John Thomson, who had probably contributed more than any other to the advancement of the study of disease in childhood during the last 25 years.

Acute Nephritis in Childhood

Dr **L G Parsons** (Birmingham), in opening this discussion, said that an analysis of a series of cases of acute nephritis showed that advice was usually sought because the child was passing bloody urine or because he was puffy or swollen These two types of onset were associated with a series of symptoms and a clinical course which served to differentiate the cases into two groups The cases in the hæmorrhagic group tended to recovery, whereas in the œdematous group the tendency to pass on to a chronic nephritis was more marked Mixed cases showing a combination of symptoms of the two types also occurred, and, finally, there were cases which in the course of an illness, such as diphtheria, scarlet fever, pneumonia, showed symptoms which placed them in one of the foregoing groups or an examination of the urine revealed albuminuria with or without casts The occurrence of defective excretion of threshold bodies in the œdematous or hydræmic group suggested that in these cases the tubular defect was the important one, and that in the absence of œdema any damage to the tubule was only slight The pathological classification and description of acute nephritis given by Shaw Dunn was a good one, and could be used as a basis for a clinical classification Febrile albuminuria constituted the mildest form of acute nephritis, and might represent either a transient glomerular nephritis or transient tubular nephritis

The explanation of cases of chronic nephritis which arise insidiously, and of the failure to clear up what was apparently the first attack of a frank acute tubular nephritis was, said Dr Parsons, not improbably to be found in the occurrence of a febrile albuminuria in a previous acute pyrexial illness Nitrogen retention raised blood pressure, and uræmic fits were stated by some writers to be characteristic of the hæmorrhagic, by others of the tubular variety of acute nephritis Both observations were correct, and their occurrence depended on the severity of the case, although the explanation was not the same in each group In the hæmorrhagic cases the symptoms only occurred if there were oliguria The oliguria was probably due to a mechanical retention of water from swelling of the glomerular tuft, and as a result of this urea was also retained When the swelling became slightly less the "head" of urea in the blood produced a diuresis This "critical diuresis" was of most favourable prognostic importance Shaw Dunn and Jones had shown that in experimental tubular nephritis urea retention and oliguria occurred This was due to the fact that tubular necrosis was produced, and the dead cells allowed the fluid in the tubules to diffuse back into the more dilute and changing tissue fluids in the supporting structures Blackfan and Hamilton found that a steady rise in blood pressure was the most reliable sign of approaching uræmia; in their opinion raised intracranial tension resulting from œdema of the brain was the causative factor in producing uræmic symptoms, and the raised intracranial pressure was the cause of the raised blood pressure Marriott maintained that nephritis was only part of a general disease, and due in the glomerular form to streptococcal, in the parenchymatous form to staphylococcal infections The streptococcal infection was usually of the tonsils, the staphylococcal of the nasal sinus It was quite clear that the exudative type of acute nephritis frequently appeared to arise without any obvious cause, whereas the hæmorrhagic was particularly associated with acute infections, especially tonsillitis, otitis media, &c , and an important group with septic rashes

In the treatment of acute nephritis Dr Parsons laid down three essentials (1) rest, (2) a suitable dietary, and (3) the removal of any focus of sepsis The patient should be confined to bed for at least three months, for rest of the body was as important in acute nephritis as in rheumatic heart disease Although excretion of protein end-products entailed little effort on the part of the kidney, and "renal rest" could not be produced by starvation, yet he (the speaker) could not accept the view that limitation of protein in the diet was unnecessary The diet should consist of milk or junket, with sugar and fruit juice as flavouring agents, for six to eight weeks Attempts to relieve the kidney by increasing the elimination of fluids by the skin and by the bowel were of little value, diuretics were probably harmful and should not be used, and in the treatment of acute nephritis drugs generally had no place

Dr **J M. Smellie** (Birmingham) thought that until a much closer correlation between the clinical picture and the true histology of the morbid process was possible, such a classification as that suggested by the opener should not be considered final Clinically, there was *no doubt that* a large number of cases could be divided into two groups (*a*) the hydræmic, œdematous, or exudative , and (*b*) the hæmorrhagic, but many mixed forms were encountered He did not like the term "parenchymatous," since it suggested that parenchymatous changes in the hæmorrhagic form were either of negligible extent or not present The cases investigated fell into three groups (*a*) early, (*b*) intermediate (*c*) late The early prognosis was judged on six cases examined 18 months to four years after an acute attack of nephritis Only one of these revealed clinical and biological changes indicative of renal damage The intermediate prognosis was based on a case observed over a period of six and a half years , when first seen he suffered from uræmic fits, five years later he had acute pyrexial illness (chorea) without any recurrence of kidney mischief, and is now apparently healthy, although the biological findings are abnormal The remote prognosis was based on a review of 39 cases at an average period of 16 years after an attack of acute nephritis, and without exception all these to-day were symptomatically well Four had passed through pregnancy, and only one of the four suffered from convulsions at the time of labour Sixteen had been examined clinically and renal efficiency tests carried out None of these had any of the urinary changes associated with a chronic nephritis Six revealed evidence of disturbance of the cardiovascular system, but he asked if he were correct in assuming that this disturbance was consequent upon previous renal inflammation He had not found the renal efficiency tests to be of the assistance anticipated In the absence of symptoms or physical signs, positive biochemical results could not be taken as conclusive evidence of renal damage, but they called for a further scrutiny of the patient and a certain guard in the prognosis until the case had been observed for a longer period The absence of chronic and subacute cases in his survey was striking This could not mean that they had all died, but was due in his opinion to the fact that the cases reviewed were severe in type, and that chronic nephritis was much more likely to develop from a succession of mild attacks, often overlooked, than from a severe attack which had received adequate treatment His investigations had led him to the opinion that the ultimate *prognosis* of acute nephritis entirely hinged on the treatment given If the original disease received efficient treatment complete recovery would occur in a very high proportion of cases

Dr **J C Spence** (Newcastle) said that although he agreed that the hæmorrhagic form carried a good prognosis and the exudative form a bad prognosis, and the postural fibres by the sympathetic Spastic paralysis was a state of exaggerated postural activity, and it was thought that destruction of the grey rami of the sympathetic would cure or greatly diminish, the spasticity of the corresponding muscles but the claims put forward for this operation had not been substantiated As to the view that the sympathetic was specially concerned with the postural activity of skeletal muscle the histological evidence was negative and disputed; the conclusions drawn by Hunter and Royle from experiments on animals, had been severely criticised by neurologists but what perhaps was of the greatest importance was the fact that in the hands of others the operation of sympathetic ramisectomy had not given results at all approaching those claimed by Royle For many years orthopædic surgeons had treated spastic contractures locally by operation upon the contracted muscles or their nerves, and he emphasised the point that whether one attacked the muscles or the nerves, the principle of the operation was the same—namely, to diminish the effective action of a muscle either by lengthening it, so that its effective range of action was less, or by destroying part of it so that its strength of contraction was less Good results had been obtained by both methods He thought that operations on the peripheral nerves, known as Stoffel s operations, had some advantages over those on muscles and tendons The correction of typical deformities of spastic paralysis by muscle and tendon operations entailed a long course of treatment the details of which were, of course well known It was necessary to keep the limbs for some time in some form of apparatus and to prevent relapse many surgeons had found it necessary to put these cases into walking instruments for a long time after the correction of their deformities Now the principle of Stoffel s operation on the peripheral nerves was this In spastic contracture there was a powerful group of muscles in a state of tonic contracture, so intense that it held the part in a position of deformity, and prevented movements in any direction Destruction of a sufficient part of this muscle group abolished the excessive contracture and got rid of the contracture deformity, whilst leaving sufficient muscular power for all practical purposes The simplest way of destroying muscle-fibres was to cut out their nerve-supply, and Stoffel's operation consisted in finding the nerve tracts. usually before they left the main nerve and excising a sufficient portion of them In each case the relief of the contracture was immediate and permanent This statement had been criticised and he would therefore like to add that he had seen recurrence of deformity after Stöffel s operation on the internal popliteal nerve but he did not blame the operation for this but rather himself, for the recurrence was due either to faulty judgment or to faulty technique In conclusion he would submit that Stöffel s operation was the best method of treatment which had yet been devised for the relief of spastic contracture The actual operation in each region was quite a minor operation and easy of performance. and it admitted of a degree of precision and adjustment to the needs of individual cases, such as could not be obtained in any other way The very nature of the resulting intentional paralysis made recurrence of the contractures impossible and therefore prolonged after-treatment, and the use of splints or other apparatus was unnecessary

Dr John Beattie (London) said that those who engaged in carrying out animal experimental work on the sympathetic agreed that Royle's operation as described by Hunter was a complete failure in man Dr Adie's statements that the evidence available at present does not support the notion that sympathetic plays any part in the regulation of muscle tone and that sympathetic impulses to the muscles if these exist, are cut off by the very section that produces decerebral rigidity. were incorrect In attempting to apply to man the results obtained from experiments on animals care was necessary because the problem of muscle tone was a different one in man and in animals Moll, however. in trying the effect of nicotine on the constitution of post-encephalitic Parkinsonism, had recorded a series of facts which showed that the sympathetic in man had some effect in increasing muscle tone Dr Beattie then showed a series of most interesting cinematograph films illustrating the effects of sympathectomy on seagulls, fowls, non-decerebrate and decerebrate goats

Mr S W Daw (Leeds) said that he rarely saw progressive cases He had employed Stoffel s operation in a large number of cases, and the results on the whole were very satisfactory This operation was very much superior to operations on tendons because of the tedious and often painful after-treatment necessary in the latter operations Fourteen days after Stöffel's operation the child could begin to walk and start re-education exercises If contraction were present a combination of the two methods. Stoffel's operation and tendon lengthening was useful. In the lower limbs lengthening of the muscle was. however, preferable to lengthening the tendon A mild degree of athetosis was not a contra-indication to operation

Mr Naughton Dunn (Birmingham) said that there were three difficulties in the treatment of spastic diplegia (1) the mental condition of the child, (2) the increased tone, and (3) the weakness and diminished voluntary control of the muscles He made it a rule that no operation should be done unless the child had shown either naturally or after training some attempt to use the limbs Re-education after operation was of the greatest importance With regard to the question of muscle or tendon lengthening, his practice was to do a muscle lengthening operation where the muscle was a fleshy one. but where the muscle had a direct tendinous insertion tendon lengthening was preferable

In the opinion of Mr H A T. Fairbank (London) the deformities largely depended on the action of gravity and the advantage that certain groups of muscles have over their antagonistic muscles He would ask Dr Adie if he knew of any drugs which had any effect on the involuntary movements, particularly on the "jumpiness" seen in some cases. Gross involuntary movements were certainly a contra-indication to operation. but in certain cases operation seemed to improve involuntary movements The right age for operation was about three years, because when the child had reached that age the surgeon had a better idea of what it was necessary to do He asked why it was that some children developed anatomical shortening of the affected muscles early. and others much later on in life, and he would also like to know how much nerve-fibre must be exsected to prevent regeneration in Stöffel s operation, because in three instances he had known regeneration occur after exsection of one inch of nerve

Dr Neill Hobhouse (London) admitted that Dr. Adie had made out a good case for birth injury being the causal factor in infantile hemiplegia and spastic diplegia If these cases were seen in infancy and early childhood a great deal of spasticity could be prevented, and there was a wide field for non-operative treatment in hemiplegia and in a considerable number of cases of diplegia In any child where new reflexes could be conditioned new voluntary movements could be developed, and why, therefore could not inhibition of these movements also be developed Faradisation of spastic muscles was irrational and was the cause of a great many of the severe contractures seen A severe degree of spasticity rarely occurred in any case which he had had under observation from infancy. In hemiplegia the very best treatment was to tie up the sound arm and so make the child use the hemiplegic one

Dr W F. Menzies (Leek) said that as one of these children the subject of spastic diplegia grew up. first there was no spasticity and it was able to perform movements but later the limbs became rigid and later still there were contractures The faster the child went down hill the earlier rigidity and spasticity developed and the more could it be inferred that years of age In Essex goitre, both in boys and girls, was almost unknown, whereas in one school at Wirksworth 57 per cent of the girls and 50 per cent of the boys were goitrous He also found that the incidence of certain diseases varied in goitrous and non-goitrous children—thus 25 per cent of goitrous children suffered from rheumatism, compared with 5 5 per cent of the non-goitrous children The types of goitre found were either the simple parenchymatous variety or the hyperplasia of puberty, but the types ran one into the other Some of the cases showed hypo- and some hyper-thyroidism There were no cases suffering from toxic adenoma or exophthalmic goitre A scheme for the prevention of goitre had been started at Glossop, the children were given iodised sweets containing 5 to 10 mg of iodine Goitre in Derbyshire was a dying disease and was disappearing in every district where a cleaner and better water-supply than formerly was obtained.

In discussing this paper Dr L A PARRY (Brighton) thought that there must be some other explanation than locality for such a wide variation in incidence He thought the personal factor of the examiner must account for much of the difference

Dr M EDELSTEN POPE (New South Wales) said that a goitre survey of 75,000 country and 10,000 city children of 5 to 15 years of age had been conducted in New South Wales, and it was found that goitre was endemic in certain areas Goitre was found in the hilly districts just off and on the edge of the tableland, whereas on the hot, dry plains and seaboards the children were free from goitre

THURSDAY, JULY 22ND

At a joint meeting with the Section of Orthopædics, when Mr E MUIRHEAD LITTLE (London) presided, a discussion on

SPASTIC PARALYSIS

was opened by Dr W J ADIE (London), who said that he accepted the word "spastic" in the strict sense, and would confine his attention to those conditions in which stiffness and weakness of the muscles resulted from disease of the pyramidal system The commonest, and therefore the most important of these, was the form of cerebral diplegia, generally known as Little's disease According to many, injury to the brain at birth was the most important ætiological factor in Little's disease, but Dr James Collier considered that the essential anatomical lesion was a primary degeneration of cerebral neurones, due to causes at present unknown The remarkable researches upon the mechanism of birth injuries, and the pathological changes produced thereby, that were being carried out by Schwartz and his associates, demonstrated the great frequency of these injuries, and the decisive part they played in producing much infantile mortality which was at present attributed to other causes This work proved that not only could gross changes occur, but that atrophic sclerosis might result from injury to the brain sustained at birth Dr Adie himself had called attention to the remarkable group of symptoms presented by men who had sustained gun-shot wounds of the vertex, with injury to the superior longitudinal sinus, producing a transitory clinical picture of Little's disease in its purest form There were two other features of ordinary diplegia which he found difficult to reconcile with the notion of a primary neuronic degeneration as the essential anatomical cause (1) that the disease was not a familial one, and (2) that practically all the conditions in which primary neuronic degeneration was generally accepted as the anatomical cause, the course of the disease was progressive to death, or up to a point peculiar to the disease, or to the affected family, whereas the tendency to improve was highly characteristic of ordinary non-familial diplegia For practical purposes it mattered little whether the damage was pre- or intra-natal The important fact was that diplegia from birth tended to improve, and much could be done in these cases by appropriate surgical treatment The cases must, however, be carefully chosen Gross mental defect was a contra-indication, but where this was moderate an operation which would enable the child to move about might bring about an improvement in the mental condition Diplegia and epilepsy was an unfavourable combination, and if the fits were not easily controlled by appropriate remedies the surgeon should hesitate before operating on the limbs, as the prognosis for the mental condition was bad Operation was hardly worth while when involuntary movements were the unfavourable symptoms

After describing some forms of familial diplegia, such as amaurotic family idiocy, the Merzbacher-Pelizaeus "disease" and the hereditary form of spastic spinal paralysis, Dr Adie went on to deal with the neurological problems presented by spastic paralysis He said that recent studies on decerebrate rigidity had added greatly to the knowledge of muscle tone, but so far they had given no clear indication for new methods of treatment The disturbance of tone and the reflex phenomena of spastic paralysis in man were identical, as Walshe had pointed out, with the tonic and phasic reactions in decerebrate animals It might well be that sympathetic nerve-fibres reached striped muscle-fibres and exerted an important trophic influence upon them, but the evidence available at present did not support the notion that the sympathetic played any part in the regulation of muscle tone Gaskell showed long ago that the sympathetic nervous system was not a separate nervous system, interchanging fibres with the cerebro-spinal system, but was formed by fibres given off from the cord Langley made it clear that the autonomic system of which the sympathetic is a part, though capable to a certain degree of independent action, functioned under the control of higher centres These higher centres from which he believed all impulses passed that reached the sympathetic, were situated at a level cephalad to the point of election for the section producing decerebrate rigidity, and if his assumption were correct, sympathetic impulses to the muscles, if they existed, were cut off by the very section which produced decerebrate rigidity It was certain that complete ablation of the sympathetic system had no effect on decerebrate rigidity, and hence the division of sympathetic fibres were not likely to influence spasticity He hoped that surgeons who had performed sympathectomy in spastic states would communicate their results during the discussion

Mr BLUNDELL BANKART (London) said that spastic paralysis was not a disease, but a physiological state—the natural physiological result of the anatomical condition present in any given state It closely resembled, if it was not identical with, the condition known as decerebrate rigidity, which was produced experimentally by section of the brain above the level of the mid-brain The treatment of spastic paralysis was operative It was true that considerable improvement might sometimes be effected in spastic individuals by systematic training, or re-education of movements, but apart from that non-operative treatment was useless, and he had never yet seen any permanent benefit result from massage, manipulations, or electrical stimulation Moreover, in the majority of cases the place of re-education was after operation and not before it When structural shortening existed, it had to be treated by a direct attack on the shortened muscles or their tendons But when dealing with pure physiological contracture there was a choice of methods It was hardly necessary to discuss Foerster's operation of posterior root section, since it had been universally abandoned as a method of treating spastic paralysis It was, however, necessary to say something about the operation of sympathetic ramisectomy, which had been recently introduced by Hunter and Royle, and had now been given a fair trial The operation was based upon the hypothesis that the functions of movements and posture were performed by entirely different sets of muscle-fibres, and that the movement fibres were supplied by the ordinary spinal nerves hip, he was sure that it was quite true that many patients go on for a long time with very little pain He knew of a woman of 40 with unilateral dislocation, who rode and played a good game of tennis

Mr S T **IRWIN** (Belfast), referring to displacement of the head of the femur, said that up to the age of about 11 years the epiphyseal cartilage of the head was continuous by a bar of cartilage with the cartilaginous neck and that this prevented slipping of the epiphysis, which was rare under that age He showed some excellent demineralised specimens and others illustrating this detail in the development of the femur, and a number of lantern slides of cases of displacement of the epiphysis and of arthritis from various causes

Mr T P **MCMURRAY** (Liverpool) preferred a simpler classification than that of Mr Fairbank He would divide cases into tuberculous and non-tuberculous and subdivide the second category into traumatic and infective This classification would not include pseudo-coxalgia He thought that sesamoid bones in the neighbourhood of the hip-joint did not predispose to arthritis

Mr **HARRY PLATT** (Manchester) referred to the diagnostic value of information concerning the comparative incidence of the various types of chronic hip disease, and particularly to the age of onset Broadly speaking, a chronic hip lesion in a child under 5 years of age was likely to be tuberculous arthritis, between the ages of 5 and 10 pseudo-coxalgia was at least as common as tuberculous arthritis In the second decade tuberculous arthritis was found to be a comparatively rare lesion the characteristic hip lesion of this age being traumatic coxa vara At all age-periods a transitory synovitis due to trauma or infection might occur It must be recognised that the symptoms of " mild hip disease " were seen in the early stages of both the tuberculous and non-tuberculous lesions Tuberculous arthritis proper could be diagnosed with ease in the florid phase but considerable difficulty was experienced in the extra-articular forms of tuberculous coxitis An early confirmatory sign of primary disease of the acetabulum was enlargement of the iliac glands The importance of this sign did not seem to be appreciated widely. Occasionally the clinical course of tuberculous coxitis was comparable to the better-known " dry arthritis " of the shoulder-joint In such cases destructive changes developed after a long latent period, during which there might be an apparent complete remission of symptoms Pseudo-coxalgia with its typical radiographic picture usually offered little difficulty in diagnosis Chronic infective synovitis and arthritis, arising de novo in children, was a rare affection, but in hip-joints already defective, as for example, in the milder degrees of congenital subluxation, secondary arthritic changes were often seen In the adolescent arthritis deformans juvenilis showed quite a typical clinical and radiographic picture, but was unlikely to be a true primary coxitis At this age-period a " dry arthritis " of non-tuberculous origin seemed to exist as a definite entity but it must be admitted that the final pathological proof was often wanting

Mr **ALAN H TODD** (London) advocated elaborate classification clinically so as to find out what were the varieties and perhaps finally to simplify the classification He believed that juxta-epiphyseal strain was a real stage of coxa vara He had experience of sesamoid bones of the hip and other occasional opacities about the upper rim of the acetabulum in X ray pictures without any symptoms. He spoke of the possibility of gonorrhœal arthritis in small children such as had been observed in hospital after an epidemic of vulvo-vaginitis In the differential diagnosis of tuberculous and non-tuberculous hips he thought that the suggestion made by Dr Knyvett Gordon of a histological examination of the blood for leucopenia and other abnormalities might give useful information, and he put in a plea for a collective investigation of this method Doubtful cases should be treated tentatively. Although some cases of unreduced congenital dislocation of the hip might not suffer grave inconvenience in after years, many others did, and it was most important to impress upon the profession the importance of earlier diagnosis and treatment than was now the rule

Mr F C **PYBUS** (Newcastle-on-Tyne) referring to Mr Irwin's specimens of femurs, said that the cartilaginous head was freely vascularised before ossification and thus primary vascular infection of the hip might occur Rollier, at Leysin, allowed some movement in tuberculous joints and he thought that we might also do so In pseudo-coxalgia the X ray appearances might either precede or succeed the clinical symptoms Coxa plana might occur in this disease He doubted if arthritis deformans juvenilis was a clinical entity In tuberculosis of the neck of the femur early operation and removal of the focus and drainage might prevent involution of the joint.

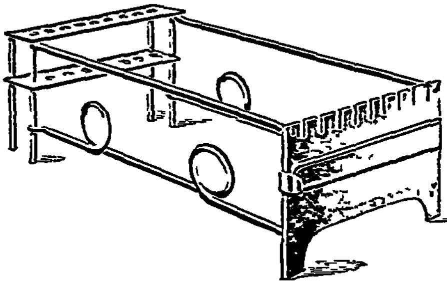
Mr W A **COCHRANE** (Edinburgh) said that an additional fact of interest in regard to displacement of epiphysis was the variation of angle of the epiphyseal line with the axis of the neck of the femur He thought that the nearer this line approached the vertical the more likely was the epiphysis to slip. Was there any relationship between slight and neglected epiphyseal separation and the later development of coxa vara ?

In a brief reply Mr. **FAIRBANK** said that in juxta-epiphyseal strains there was always slight displacement of the epiphysis Acutely infected joints should be opened and freely drained without tubes

New Inventions.

AN OPERATIVE RADIUM-NEEDLE STAND.

THE stand here illustrated is designed to facilitate the radium surgeon in operations of access and insertion. The illustration shows the stand with radium needles and tubes in position, together with their attached threads and identification beads. Sterilisation may be effected by boiling the stand with the needles, &c , in situ, or the needles and tubes may be sterilised separately in spirit and then placed in position If using the former method, the threads are anchored by means of a metal band with aseptic hinge which secures them against the end of the apparatus, while the radium tubes remain safely in test-tubes passed through the wire loops provided on the lower horizontal support of the frame. At operation the band is swung back to liberate the threads and the stand is placed on a table close to the operator ready for use



We are indebted to Messrs J Gardner and Son, 32, Forrest-road, Edinburgh, for making the stand for us

ARTHUR B. SMITH, M B., F.R C S Edin.
SYDNEY M. SMITH, M B , Ch B. Edin.

London, W

the cerebral cortex was involved. If these children were treated and taught to walk, the onset of the symptoms of spasticity occurred at about three years of age, but if they were left untreated spasticity did not occur until 15 or 16 years of age

Mr A ROCYN-JONES (London) pointed out that operation not only benefited the physical condition of the patients, but it also benefited their mental condition Stoffel's operation was the ideal treatment, but in some cases a combination of this operation with muscle and tendon lengthening was necessary, Adductor spasm was likely to recur after Stoffel's operation, and he therefore always cut the adductor longus in addition to removal of part of the nerve

Mr A H TODD (London) said that in the treatment of upper limb defects the enthusiasm of the parents was often a determining factor It was important to get the child to use both hands, and treatment in such cases could be summed up in the phrase—a keen mother and a wheel-barrow

Dr N B CAPON (Liverpool) said that he spoke from the point of view of the children's physician Since cerebral diplegia was almost certainly due to birth trauma, the right line of treatment for spastic diplegia was to treat it before the spasticity developed —i e , when the baby was 1 to 2 days old The lesion produced by the birth injury was not a meningeal hæmorrhage (except in cases where death occurred), but was due to œdema, congestion, and subtentorial hæmorrhage, and for relief of the condition repeated lumbar punctures were necessary and efficacious If lumbar puncture was not done, the results found were those described by Schwartz, to which Dr Adie had referred

Dr ADIE, in reply, said that Schwartz's work had shown that even alleged congenital defects of the brain were the results of birth injury There was no drug which had any beneficial influence on spasticity, but for the general "jumpiness" described by Mr Fairbank he would recommend bromides

Mr BANKART, replying, said that with regard to the question of nerve or muscle section there was much to be said on both sides In view of the experimental results shown on the screen by Dr Beattie he would like to ask him why ramisectomy had failed in the human subject ?

SECTION OF ORTHOPÆDICS

FRIDAY, JULY 23RD

THE first meeting of this Section combined with the Section of Diseases of Children to discuss Spastic Paralysis, and has been reported under that section On the second day, Mr E MUIRHEAD LITTLE presiding, a discussion on

NON-TUBERCULOUS COXITIS IN THE YOUNG

was opened by Mr H A T FAIRBANK, who referred to an admirable paper by Mr Alan Todd, read at the Orthopædic Section of the Royal Society of Medicine He would endeavour to cover the same ground Coxitis might arise from trauma or infection, and he suggested as a basis of discussion the following classification (1) Traumatic synovitis and arthritis, (2) traumatic synovitis and arthritis with adolescent coxa vara, (3) infective arthritis—acute, subacute, and chronic (subsection arthritis secondary to osteomyelitis), (4) acute rheumatic arthritis, (5) rheumatoid arthritis (Still's disease), (6) pseudo-coxalgia, (7) coxitis complicating congenital dislocation of the hip—(a) villous, (b) absorptive, (c) osteo-arthritic, (8) arthritis deformans juvenilis This differed somewhat from Mr Todd's classification "Coxitis of secondary onset" had been left out, inasmuch as all cases, including the tuberculous, were secondary to other lesions Infective arthritis depended on the organism producing it and the virulence of this organism, not on its source Taking these groups seriatim, Group (1), said Mr Fairbank, recovered with rest without immobilisation Some of his recent cases had shown a separate piece of bone in the acetabular margin, possibly a sesamoid in the reflected head of the rectus Did this condition, he asked, predispose to joint strain ? Group (2) Epiphyseal strain was the first stage of adolescent coxa vara, shortening and displacement were always present This was a very important group, for cases with gross displacement and much spasm were often mistaken for tubercle Group (3) All types of arthritis might be caused by the same organism of varying virulence, especially staphylococci, even in the same patient If the arthritis was suppurative and arthrotomy became necessary, perfect drainage was essential The subacute type in which the pneumococcus might be suspected, was to be treated by irrigation and closure of the wound After acute arthritis, abduction must be maintained at least three months to avoid dislocation Difficulties of diagnosis and treatment occurred in acute osteomyelitis of the femur with secondary arthritis Subacute and chronic cases of arthritis with negative X ray finding required immobilisation and extension, with the skiagram repeated after a month, and again if necessary after further fixation There was no special form of arthritis associated with measles In scarlet fever, all grades of arthritis up to suppuration were met with, due probably to toxins or actual infection with streptococci of varying virulence Enucleation of tonsils should not give rise to secondary arthritis if properly performed, but if infective remnants were left, arthritis might follow at any subsequent time Group (6) Tubercle might simulate pseudo-coxalgia Two clinical stages of the latter required differentiation without general spasm—from pre-arthritic tubercle of femur or acetabulum, with general spasm—from tuberculous arthritis Group (7) The traumatic arthritis which occurred after reduction of a dislocated hip was possibly infective Pain in untreated cases was due to arthritis and not to mere static conditions—which had an important bearing on treatment Was villous arthritis possibly the cause of pain when X rays failed to reveal gross changes in the head of the femur ? Absorptive arthritis might occur as a late result of reduction in older children, successful or unsuccessful Osteo-arthritis occurred chiefly in subluxated hips, undiagnosed until the onset of arthritis Group (8) The juvenile form was very rare as a primary affection It was, as a rule preceded by anatomical abnormality resulting from congenital defect, trauma, or infection

Mr S W. DAW (Leeds) thought Mr Fairbank's classification a good one, but he would leave out arthritis deformans juvenilis as he was not satisfied that it existed as a separate primary entity He often came across cases which it was difficult to fit into any of the recognised groups With Mr Fairbank he would leave these unclassified until we were more certain of their status, and he suggested that arthritis deformans juvenilis should remain in this category As to rheumatoid arthritis (Still's disease), he would like to say something about the difficulties of diagnosis in the earlier stages Many years ago a case diagnosed by a colleague and himself as tuberculous was treated by immobilisation A year or two later she appeared as an out-patient with arthritis of both knees and hips He then changed the diagnosis to rheumatism and allowed exercise She was now walking very badly with much limitation of movement in all the joints In another case, diagnosed and treated as lumbar, Pott's disease appeared a year later with arthritis of practically every joint in the body, including the small joints of the hands After getting scarlet fever his joints cleared up astonishingly, but he had a dislocation of one hip as a result of scarlatinal arthritis He thought that these cases illustrated the fact that the development of multiple joint lesions might be slow The differentiation of pseudo-coxalgia from tuberculosis might be difficult, but he believed that in the former it was nearly always the case that the X ray appearance was in advance of the clinical symptoms while the reverse obtained in tuberculosis As to congenital dislocation of the publisher's reader had been more careful about the details of the revision The bibliography of papers with its subject index has disappeared, but it is still mentioned in the preface dated 1926, the diagram of ancestral inheritance no longer appears "on the opposite page" (p 325) but on the following page, Kammerer's book is dated "New York, 1924," in the text (p 211) and "Boston, 1925,' in the bibliography (p 533)

The Crystalline Lens

Semiologie Oculaire Le Cristallin et son Appareil Suspenseur By Felix Terrien, Professor in the Faculty of Medicine in Paris Paris Masson et Cie 1926 With 158 figures Pp 240 6s

This volume, which deals with the anatomy, physiology, and pathology of the crystalline lens, is a section of a work planned on a large scale to include the whole of ophthalmology The embryology and development of the lens are first discussed, adequately enough, on familiar lines The anatomical section which follows is well illustrated One of the diagrams clearly displays the variations in the thickness of the lens capsule on its anterior surface, which variations, according to modern views, are an important factor in the mechanism of accommodation The theory of Helmholtz, which ascribes the increase in the curvature of the anterior surface of the lens during accommodation to the relaxation of the zonular fibres, still holds, having recently received support from the work of E F Fincham Tscherning's theory has now but few adherents, while that recently put forward by Lindsay Johnson, who ascribes the alteration in the curvature of the lens to the hydraulic pressure of the aqueous, is firmly rejected by Prof Terrien The second and smaller half of this volume is devoted to the various forms of cataract and dislocated lens Operative treatment is reserved for another volume, and the author here merely indicates his preferences for conservative methods of extraction preferably combined extraction with a conjunctival bridge and a small peripheral iridectomy We should have welcomed a somewhat fuller treatment of the subject of congenital cataract, apart from the anterior polar and lamellar forms there is little more than a page allotted to this condition Total congenital cataract is one of the most difficult subjects with which the ophthalmic surgeon is called upon to deal and the prognosis after operation is always doubtful A considerable percentage of the inmates of blind schools are children who have been operated on in early childhood for cataract with unsatisfactory results, being left with nystagmus and the remains of lens capsules in both eyes

Possibly the author will find opportunity to deal more exhaustively with the treatment of congenital cataract when he comes to discuss operative measures

Diseases of the Ear

Politzer's Text-book on the Diseases of the Ear For Students and Practitioners Sixth edition Revised and largely rewritten by Milton J Ballin, M D, Ph B, Attending Oto-Rhino-Laryngologist, Bronx Hospital, New York London Bailliere, Tindall and Cox 1926 Pp 776 31s 6d

Adam Politzer was an outstanding figure in otology through the second half of the last century, he published his method of inflation of the tympanum in 1863 His text-book of diseases of the ear has been through many editions in many languages, it excels especially in the careful detail of the description of the examination and treatment of the commoner forms of ear disease the inflammations of the middle ear and the varieties of middle-ear deafness Suppuration of the middle ear for instance shows great variety in its course and in the pathological appearances which it produces, Politzer's minute account of the details of its treatment are most useful not only to the practitioner, but to the otologist

But otology has advanced considerably in some directions in the last 20 years, Politzer's is now an old book and, unfortunately, Dr. Ballin has not revised this new edition with sufficient care to bring it up to date Even a cursory examination of the references to authorities given in footnotes makes this evident; few, indeed, of these references are less than 20 years old certain "recent investigations" mentioned in the text carry a reference to a paper published in 1902, and many papers are dated from the last century The difficulty in determining whether we are reading what Politzer wrote many years ago or an addition made by the translator further detracts from the book As to the later developments in otology, the description of nystagmus produced by caloric stimuli and by rotation is not clear enough to be of use in a clinical examination of the labyrinth; the same criticism must be applied to the account of the pathological changes in the cerebro-spinal fluid obtained by lumbar puncture, and it is odd to read even a short description of the static function of the vestibule without a reference to the work of Magnus and de Kleijn On the other hand, operations devised during last century for the improvement of cases of "adhesive" middle-ear catarrh, such as artificial perforation of the drum division of the posterior fold, and tenotomy of the intratympanic muscles, are discussed at considerable length though they have long been abandoned The attempt to modernise this once excellent and authoritative work has not been successful

Treatment of the Acute Abdomen

Operative and Post-Operative By Zachary Cope, B A, M D, M S Lond F R C S Eng Senior Surgeon to Out-Patients St Mary s Hospital, Paddington Oxford Medical Publications London Humphrey Milford Oxford University Press 1926 Pp 254 10s 6d

This is a volume companion to the author's well-known monograph on the Early Diagnosis of the Acute Abdomen It is primarily intended to help medical men not much practised in abdominal surgery who are called upon in emergency to deal with acute abdominal conditions Far from being an exceptional experience, the spread of cottage hospitals all over the country has made this circumstance more and more common and practitioners in remote parts constantly have to deal with conditions outside the experience of their ordinary practice To such men this volume should prove an invaluable aid Lucid and concise directions are backed by sketch drawings which are so clear that it is scarcely necessary to read the text in order to appreciate the detailed technique of even complicated operations The chapter on preparation and after-treatment will be invaluable to those who cannot depend on the help of an experienced sister Any doctor who is liable to run the risk of having to perform an emergency operation should obtain this book and master its contents before the emergency arises

The Law Relating to Dentistry

The Law and Practice Relating to Dentists and Dentistry By Albert Crew Barrister-at-Law London John Bale Sons and Danielsson 1926 Pp 228 10s 6d

Mr Albert Crew has brought together in a handy volume the Dentists Acts of 1878 1921, and 1923 with explanatory notes and comments and with the Dental Board s Regulations and Standing Orders His chapters on professional ethics infamous conduct professional negligence and professional partnerships contain matter of value and interest to medical as well as dental practitioners An earlier chapter on the functions and characteristics of a profession is somewhat discursive and is better suited to the same author s similar volume on the profession of an accountant Accountants a body organised and controlled without statutory assistance or authority,

Reviews and Notices of Books.

INTERNAL SECRETION OF THE PANCREAS AND INSULIN

La Secretion Interne du Pancreas et l'Insuline By Dr ANDRÉ CHOAY Paris Masson et Cie 1926 Pp 570 8s 4d

THIS volume is an exhaustive summary of the literature upon the internal secretion of the pancreas It begins with an historical review which contains a good summary of the researches of K Brunner, instead of the usual cursory reference to this worker Dr Choay describes how Brunner in 1688 removed the pancreas from dogs and noted the increased appetite, thirst, and wasting which followed The author points out that Brunner cannot have succeeded in removing the entire pancreas, since the diabetes following the operation was not fatal Indeed, Brunner's own accounts of the post-mortem examinations of his animals showed that part of the gland had been left A tribute is also paid to the work of Cawley, an English physician who isolated sugar from the urine and noticed the presence of a pancreatic lesion as early as 1788 It is clear that the author has not merely accepted the historical records of other workers, but has himself investigated the literature Dr Choay describes in detail the various methods of performing pancreatectomy on suitable laboratory animals, and gives a careful account of the clinical history of depancreatised animals together with some deductions made from a study of their metabolism

The second chapter is devoted to histology and the third to a review of the various attempts to demonstrate the internal secretion of the pancreas in the different efferent pancreatic vessels Here the perfusion experiments of the earlier workers are described at great length Chapter IV is concerned with researches on the preparation of an active pancreatic extract, and the different methods for the manufacture of insulin and its purification and chemical properties are discussed The pharmacological action of insulin is fully and clearly described and two excellent figures show rabbits in typical hypoglycæmic attitudes The chapter upon therapeutic use is brief but sets out the principles of the various methods for the use of insulin and the treatment of diabetes The origin and distribution of insulin and the theories of its mode of action are discussed at length

The volume, which closes with a list of 1377 references, is an exhaustive and well-illustrated summary of the work done upon insulin up to the date of publication, and will be of the greatest value to biochemists and physicians

THE SURGERY OF GASTRO-DUODENAL ULCERATION

By CHARLES A PANNETT, B Sc , M D Lond , F R C S Eng , Professor of Surgery in the University of London, Surgeon to St Mary's Hospital London · Humphrey Milford Oxford Medical Publications 1926 Pp 154 10s 6d

IN the compass of a small handbook Prof Pannett has succeeded in presenting the modern views regarding gastro-duodenal ulceration in an attractive manner After a brief discussion on the pathology and symptomatology of the disease he devotes two-thirds of his space to treatment He presents clearly and fairly the views held by other surgeons, especially when they conflict with his own views These are well presented, backed by cogent argument and by illustrations drawn from a considerable experience The result is a decisive outlook often lacking in larger monographs He is strongly in favour of the excision of all gastric ulcers, whenever this is feasible, reserving simple gastro-jejunostomy for those cases where the extent of the ulcer or of the adhesions renders excision too severe a procedure In ulcers at a distance from the pylorus he prefers sleeve resection, holding that the usual operation of partial gastrectomy sacrifices too much of the stomach wall For ulcers of the duodenum he is an ardent advocate of partial duodenectomy, considering that the results amply justify the added risks of the operation The book is illustrated largely by the author, and his surgical colleagues will envy his powers as a draughtsman For example, in the pages devoted to technique, the details of such a complicated operation as a Péan resection can be grasped in an instant from the author's sketches Each chapter concludes with a full bibliography The book should appeal to a wide audience, for though it is written essentially for the operating surgeon, its pages will be of interest to the general practitioner who wishes to understand the trend of modern gastric surgery

We congratulate the author on the production of a monograph at once readable and complete

ATLAS OF MIDWIFERY

By COMYNS BERKELEY, M A., M C , M D Camb , F R C P Lond , M R C S Eng , Senior Obstetric and Gynæcological Surgeon to the Middlesex Hospital , and GEORGE M DUPUY, M D London · Baillière, Tindall and Cox 1926 Pp 160 7s 6d

THIS book consists of 250 illustrations and eight radiographs with rather extensive legends, but is without any text properly so-called The legends throughout are excellent, and the fact that such an experienced teacher as Mr Comyns Berkeley is one of the joint authors is sufficient guarantee that the teaching, as far as it goes, is up to date, sound and accurate For students whose memory is of the visual type this book would be a useful addition to a cram book when revision for examinations is being undertaken This we suppose is the purpose the book is designed to serve, for the ordinary student's text-book contains more figures than are found here, and although some subjects which particularly lend themselves to this method of explanation are well treated, most of the illustrations are neither better nor worse than those commonly found in text-books Many of the drawings appear to be worthy of better printing, and some, the Fœtal Circulation, for example, really need colour printing to make them intelligible.

HEREDITY

Fifth edition By J ARTHUR THOMSON, Regius Professor of Natural History in the University of Aberdeen London John Murray 1926 With 44 figures Pp 542 21s

A GREAT many books are published nowadays about heredity and in many ways this is one of the best Most of the recent works are really more about mendelism, and they lack the general historical background which Prof Thomson gives so well His book was first published in 1908 and, we think wisely, he has left large parts of it unaltered We can thus appreciate what the problems looked like nearly 20 years ago and realise that many of them look much the same to-day The rediscovery of Mendel's work has led to one of the most fruitful of biological revolutions, but it has yet to be proved—which some enthusiasts for the growing edge of natural knowledge are apt to forget—that what he found out is the whole explanation of inheritance Those who have revelled in books like Prof T H Morgan's Theory of the Gene will probably think Prof Thomson rather old fashioned and not so sure of the reasons of things as he should be There is, it is true a good deal of work of importance that he does not notice—the books of Crew and Goldschmidt for example, are mentioned in the bibliography, but not much use seems to be made of their contents in the text—but he includes much which is now often omitted, and his book forms an excellent complement to the very latest publication It is unnecessary to say that it is easy to read and understand We could wish that the author and the

THE LEGAL DISABILITIES OF HOSPITALS

IF all the generous promptings of intending donors were to materialise and the proceeds to pass unabated into the coffer of the hospitals, the anxiety of their treasurers would be in large measure relieved. On a later page of this issue is an account of what may well be hoped is the last of a series of frauds in the diversion of charitable contributions into private pockets. This source of loss, though deplorable, should hardly be large or persistent, but there are other more subtle disabilities with which hospital finance has to cope, and in a recent address[1] to the British Hospitals Association, Sir JOHN PAGET, K C, acutely analysed the legal disabilities of hospitals, due to the gratuitous nature of the services they render. Hospitals—at any rate those which are supported by voluntary contributions—are what the law calls eleemosynary institutions, they exist, as Chief Justice HOLT observed 150 years ago, "for those that are poor and mean and lowly and sickly." And, because they are generous in their charitable work, they are under a heavy legal disadvantage. To begin with, a promise to contribute money to a hospital is not legally binding. A promise to pay something for services which are given gratuitously is a promise which lacks the legal essentials of a valid contract, though it is possible (but by no means certain) that a legal contract might arise if the subscriber authorised a specific expenditure which is incurred by the hospital in reliance upon his making it good. An even more serious disability of the voluntary hospital system is the familiar fact that hospitals cannot sue for the cost of the treatment they supply even when there is some well-to-do person who is morally liable. Let us take the case of traffic accidents. These are an important element in the congestion of hospital accommodation. Not long ago, says Sir JOHN PAGET the senior house surgeon of the Bedford County Hospital was complaining that urgent cases requiring operations such as appendicitis had to be turned away owing to the number of beds occupied by motor accident cases. Sir JOHN PAGET quoted a figure of over 40 000 as the number of the traffic accidents in the metropolitan police district last year. It is reasonable to assume that a large proportion of these found their way to a hospital, and doubtless in many such cases the victims recovered damages for the negligence of a motorist. But it is certain that the hospitals got nothing. A plaintiff who claims damages for negligence on the part of a motorist often gives particulars of having incurred expenses for surgical and medical appliances and for nursing and medicines and these expenses the law courts will allow him to recover. But no plaintiff is allowed to say that he has been a source of expense to a hospital as the result of the defendant's negligence, and that the defendant ought to make good that expense. The public probably does not realise the strange consequences of the legal position. As Sir JOHN PAGET pointed out, it pays the reckless motorist to run down a poor man rather than a rich man, the poor man is more likely to receive treatment in a hospital for which the motorist cannot be made to pay while the rich man is more likely to be treated in his own home, and all the expenses of that treatment from specialists at the beginning to sea voyages at the end are items for which claim can legally be made. Similarly, it pays the reckless motorist, if he runs down a rich man, to injure him so severely that he must be treated forthwith in a hospital instead of being taken to his own home.

It is patently an unfair arrangement which makes hospitals bear the burden of another's negligence and yet gives them no *locus standi* when compensation is assessed. Is there any possible remedy? Perhaps the most practical suggestion is Sir JOHN PAGET's proposal to develop a feature of our workmen's compensation law. Under Section 8 (2) (v.) of the 1925 Act the compensation in fatal cases where the workman leaves no dependants is to be a lump sum equal to the reasonable expenses of his medical attendance and burial not exceeding £15. Under Section 26 (1) if the workman has no legal personal representative, the compensation may be paid direct to the person to whom the expenses of medical attendance and burial are due. Sir JOHN PAGET pertinently asks why, if the undertaker can thus make a direct claim, the hospital should not be allowed the same privilege. No doubt any alteration of the law in the direction of allowing hospitals to recover money promised by patients or to sue for their fees and charges would require special legislation. But there seems no reason why Parliament should not enact that, in cases of injury due to negligence, hospital expenses may be added to the plaintiff's statement of claim and recovered from the defendant. When the legislature comes presently to consider the passing of a new Act dealing with road vehicles and traffic, there will be an opportunity to ventilate some such proposal.

Opponents of a change in the law will not fail to remind the hospitals that there is another side to the picture. A barrister's services are deemed in law to be honorary and gratuitous, he therefore cannot sue for his fees but on the other hand, he cannot be sued for negligence. Similarly, the hospital which gives gratuitous treatment, if it cannot recover the cost of the treatment, can nevertheless not be made liable for injuries to patients or inmates arising from the negligence of its physicians, surgeons, nurses or assistants provided that due care and skill has been exercised in the selection of the staff. This immunity might have to be surrendered, together with the modified immunity from certain forms of taxation which hospitals enjoy, if the principle of gratuitous service were abandoned. The alternatives, however, deserve consideration, for the voluntary hospitals must explore every possible avenue of prospective income. The amounts of voluntary contributions will, we fear, show some falling off if the prolonged coal stoppage causes an increase in income-tax next year.

NEPHRITIS. A NEW HYPOTHESIS

CLASSICAL teaching in this and other countries distinguishes two common varieties of nephritis an œdematous or hydropigenous type with retention of chlorides and an azotæmic or uræmic type with nitrogen retention but normal chloride excretion. And it has become customary to explain the typical difference as due to the part of the kidney affected whether that concerned with the excretion of urea or of non nitrogenous crystalloids. There have always been difficulties in this anatomical theory for one type of disorder may pass rapidly into the other and in the dropsical type the blood chlorides are not may be interested in the privileged position which dentists enjoy, but dentists, having obtained a full measure of statutory monopoly, are no longer concerned with the informal status of less fortunate callings Mr. Crew rightly emphasises the enviable position of the dentist's profession, now so completely protected by Parliament that no poachers are allowed in that preserve The medical profession is itself less secure The book gives a useful summary of decided cases including Binns *v* Dental Board and Canton *v* Dental Board, two decisions which interpreted with a surprising elasticity the words in the Dentists Act of 1923 whereby service during the late war in His Majesty's forces was made one of a group of qualifications for admission to the register. The position of dentists in view of the changes in the political administration of Ireland is dealt with, but might perhaps be further elaborated Against Subsection 15 (1) of the 1921 Act a note might be inserted in respect of the words allowing proof of regulations " by the production of a copy purporting to be printed by any printer in pursuance of an authority given by the Privy Council " It is understood that the Privy Council does not, in fact, authorise any printer in this connexion except the King's Printer (i e, the Controller of H M Stationery Office), which means that in practice the Regulations appear in Statutory Rule and Order form and presumably would prove themselves as such, apart from the subsection above quoted

OPHTHALMIC NURSING

By MAURICE H WHITING, O B E, F R C S, Surgeon, Royal London (Moorfields) Ophthalmic Hospital With an Introduction by SIR JOHN PARSONS London J and A Churchill. 1926 Pp 173 5*s*

MOST nurses go through their general training with little experience of eye work, and to many the eye remains almost as mysterious a structure at the end of their course as it was at the beginning If they are unable to obtain experience in the eye ward of their hospital or in a special ophthalmic hospital they can, at any rate, gain some assistance from a book of the right sort This volume is based on the methods employed at Moorfields Ophthalmic Hospital by a member of its staff who formerly held the post of resident medical officer in its wards and is thus well qualified for his task It is addressed not only to nurses but also to medical students, house surgeons, and practitioners, and contains sound elementary information on optics diseases of the eye, and operations, besides actual directions for ophthalmic nursing From the nurse's point of view, perhaps too little stress is laid on those minute details for which she is primarily responsible in the preparation and after-treatment of patients undergoing major operations The chapter on Refraction and Treatment Clinics for School-children is valuable

---

VISCERAL RADIOGRAMS

A Descriptive Atlas of Visceral Radiograms By A P. BERTWISTLE and E W H SHENTON London Henry Kimpton 1926 Pp 250 21*s*

THE title of this book is well chosen In some 250 pages the authors have brought together a pictorial survey of almost the whole field of radiology, other than that of the bony structures with which one of the authors (A P B) has already dealt in a previous volume In order to make the atlas representative the illustrations have been drawn from the practices of a large number of radiologists, surgeons, and physicians, to each radiograph is appended a short concise clinical history, a description and a small line drawing to emphasise the salient points of the picture, 327 excellently reproduced illustrations are included, and the authors have been wise in their selection, the relative balance of importance being well maintained While referring to practically every innovation, they have held their hand in regard to methods which may or may not be of ultimate service For instance, only one illustration is devoted to the phenolphthalein test of gall-bladder efficiency, two to ventriculography, and not even one illustration is given to pneumoperitoneum which had a brief vogue a few years ago Two pages, however, are devoted to the lipiodol injection into the subarachnoid space of the spine, these being from the practice of Prof Sicard Sufficient illustrations of the use of pyelography are included to indicate that this has become a routine method of more than passing importance

While admiring the skill with which this atlas has been compiled, we are sure that the authors have recognised that radiography is too vast a subject to be taught in this way Clinical observation with the aid of X rays is essential, but as an outline of this vast aspect of medicine the volume will be of service, particularly to those who cannot command the services of an expert radiologist who is trained in this specialised outlook on medical science.

The publishers are to be congratulated on the way in which the book is produced at such reasonable cost

---

THE NATURE OF LIFE

A Bipolar Theory of Living Processes By G W CRILE New York Macmillan Company. 1926 Pp 405 21*s*

THE processes which distinguish the living from the non-living are due to electrical forces within the protoplasm which endow it with the essential qualities of irritation, assimilation, and reproduction This potential within the cell is created by variations in oxidation on the two sides of the lipoid films which separate nucleolus from nucleus, nucleus from cytoplasm, and cell from environment Such is we believe, the pith of the interpretation of life which Dr Crile urges upon us And it has all come from a long attempt to explain the phenomena of shock which, in his capacity as a great practical surgeon, he has been so successful in preventing He may be right No one can say, for he deals with imaginative fields where right and wrong are matters of faith But he brings forward a great variety of curious observations which may be studied with profit even if they do not compel belief in the meaning which he reads into them by parallels which seem mostly unreal and analogies which seem mostly false His writings on the anatomical signs of fatigue in cells or on the temperatures of the blood and organs under various experimental procedures are of interest But it is hard to believe that Dr Crile really expects us to take seriously his comparison (Fig 61) of the positive nucleus and the negative electron of a hydrogen atom with the nervous system and the rest of the body respectively of man He may be right, but, if he is, it is as a prophet, not as a demonstrator

---

JOURNALS

FOLIA CLINICA CHIMICA ET MICROSCOPICA —We have received the first number of a re-issue of this periodical after an interruption of 11 years owing to the war. It is edited by Dr L Zoja, of the University of Milan, and will be devoted to clinical investigations in microscopy, bacteriology, and chemistry The journal aims at familiarising practitioners with laboratory diagnosis Its editor belongs to the school of Alberto Riva in which the accurate and minute study of the patient is considered to be pre-eminent and laboratory investigation is held in honour in as far as it helps to solve diagnostic or theoretical problems which arise during this study The present number contains articles on the estimation of hepatic function by means of spontaneous or induced ammoniæmia, on the bacteriolytic principle of d Hérelle, and on the Wassermann reaction with concentrated serums.

successful as to permit of all other sources of infection save the actual patients, being disregarded. His contention that disinfection following plague is valueless because it does not get at the rat and its fleas takes no account of the view expressed by Lethem that the *Pulex irritans* plays a part in the spread of plague in this country.[3] Plague bacilli have been demonstrated in pulex by the Indian Plague Commission and by Verjbitski, and the epidemiological circumstances of small outbreaks as instanced by Lethem, are strongly in favour of his thesis "that in this country the first case of an epidemic is infected by a rat flea, usually found in grain or rags," but "that just as plague in rats is spread by rat fleas, so is plague in man in cold climates spread by human fleas, once the disease is started." This sequence of events is worth recalling in connexion with the small outbreak of bubonic plague in Liverpool reported in our last issue. The fact that one of the cases—but not the first—was a dock labourer is not in itself sufficient ground for impugning the rat. Investigations now being made by the health department with the assistance of the Ministry of Health may throw fresh light on the subject. Chagas, again, does not even mention the rôle of the infected louse in the propagation of typhus, although terminal disinfection may well be justified in that disease. But with these exceptions his argument appears well founded in relation to the prevalent epidemic diseases of civilised communities. Judging by a recent leading article in an American medical journal,[4] our attitude to disinfection is regarded as somewhat more conservative than that of the United States, and a thorough discussion of opposing views is recommended. An incident which occurred in the little town of Godmanchester well illustrates the difficulties which may arise in practice. Here the sanitary authority regarded the occurrence of three or four cases of scarlet fever in a school as sufficient reason for its thorough disinfection. The county medical officer thought otherwise, and the indignant council passed a unanimous resolution of dissatisfaction with such "dilatory methods." There is much need for education of the public in modern ideas as to the spread of communicable disease.

Annotations.

"Ne quid nimis"

EARLY TREATMENT OF CANCER

IN the annual report of the medical officer of health for Willesden, issued not long ago, is a memorandum by Dr W. D. Champneys on cancer, indicating what methods of attack have been employed in the fight against this disease elsewhere, and what methods might be employed in the large urban district where he works. The introductory pages of this memorandum deal in succession with the nature, distribution, cause, mortality, prevention, diagnosis, and treatment of cancer; they are so lucid and concise that they might well serve as a model for others who are drafting similar pamphlets. One word of caution should be added. The statement that the recorded mortality from cancer has trebled in the space of two generations, although literally true, is misleading, for in the decade 1851–60, which is taken for comparison, little was known about the diagnosis of cancer. In the final section of the memorandum Dr Champneys outlines a scheme for the control of cancer. To this end he would convene meetings of local medical practitioners to discuss the means to be employed and he would get recognised authorities to deliver post-graduate lectures and demonstrations. Leaflets and pictorial posters would be distributed to the public, articles inserted in the local press, and popular lectures given. But by far the most important measure for securing early diagnosis and treatment is, in the opinion of Dr Champneys, one that has so far not been tried in this country—namely, the cancer clinic for free diagnosis. Such a clinic would be established or maintained by the local authority, provided with X ray equipment and beds for the temporary admission of suspects to enable a thorough examination to be made. Diagnosis would be free except for a small charge for a barium meal when administered. It is on this proposal for a free clinic that Dr Champneys will meet with criticism. The diagnosis of cancer in its early stage is, except in a few selected sites—e g, tongue, skin—impossible without operation, and even after operation and examination of a portion of tumour removed it has recently been recognised that senile involution (in the prostate for instance) may closely simulate malignant change and be mistaken for such. A free clinic would by no means ensure the certain diagnosis of cancer in the earliest stage when it can be cured. In the United States of America, where active propaganda has been carried on for a decade to ensure early diagnosis, the mortality from cancer has not fallen, the effect of the propaganda being rather to increase the number of cases detected at an operable stage. The taxpayer may also have something to say to the proposal for if cancer is not a contagious disease and the sufferer from cancer not a danger to the community as is the tuberculous or syphilitic, there seems no reason why he should pay for the individual who refuses to go to a doctor when he suspects some illness. Free diagnosis for cancer would command the support of those who desire free diagnosis of other diseases, in a word, the institution of a State medical service. Moreover, life assurance companies would presumably provide means of early diagnosis for their clients, if their actuaries were to advise them that by so doing mortality could be reduced.

A far better way of securing early diagnosis is by a campaign designed to induce men and women who are conscious of any tumour, sore or disorder of function to consult their family or insurance practitioner without delay particularly if they are reaching middle-age. In a brief Memorandum[1] on Cancer of the Breast, which has been issued from the Ministry of Health in continuation of the memoranda on the same subject which have been appearing during the last three years the dissemination of information on the good results achieved by operation at an early stage is suggested—this to be by means of leaflets, talks, advice from local cancer committees, doctors, health visitors, and social workers. Educative counsel directed towards securing effective treatment of earlier conditions which have been shown commonly to precede cancer is also recommended. The present Memorandum has relation especially to the results of surgical operation in connexion with breast cancer, and supplements especially the information given in the third Memorandum of the series (THE LANCET, 1924 i, 1074). It incorporates the results of the survey made by Dr Janet Lane-Claypon with the help of Dr Major Greenwood whereby the previous conclusions in respect to the value of the complete operation at an early stage have been confirmed.

A SOURCE OF CHOLERA INFANTUM

THE syndrome of cholera infantum, comprising sudden severe diarrhœa with dehydration and collapse, has been found by many observers to occur in the absence of any ascertainable infection of the gastro-intestinal tract, and of any epidemic source of infection. The origin of the disorder has accordingly been referred to as "parenteral" without any definite notably increased in spite of the low chloride content of the urine, whereas in calculous anuria a concentration of plasma chlorides is seen far in excess of the normal figures. A novel and admirably argued explanation of the biochemical features of nephritis is to be found in a recent article by Dr. A. M. Fishberg,[1] of New York, who after prolonged investigation finds no evidence that a damaged kidney is ever affected as regards one excretory function without the others being equally impaired. He emphasises the differences in concentration of various blood constituents which the normal kidney brings about when secreting urine. Thus urea, uric acid, and phosphates are normal concentrated from 30 to 60 times before reaching the ureters, whereas chlorides, sodium, and calcium are normally scarcely concentrated at all. When, therefore, the kidney's concentrating function is adversely affected the result is at once seen by an increase in the urea, uric acid, and phosphates in the blood, whereas the chlorides, sodium, and potassium are not altered. O. L. V. de Wesselow,[2] in a recent article, drew attention to the failure of the grossly damaged kidney to concentrate the urinary chlorides after a salt meal. He showed how such a meal demonstrates a lack of concentrating power just as great for chloride as for urea, and in a paper which appears in our present issue brings forward still more conclusive evidence to this effect. Fishberg justly emphasises the extrarenal excretory powers of the body which, together with a natural diminution of chloride intake in nephritic cases, prevents any accumulation of this element in the blood. Of the dropsical type of Bright's disease Fishberg says that many belong to that class described by Epstein[3] in which the protein content of the blood is so lowered that a transudation of chloride and water into the tissues occurs as a purely osmotic phenomenon. Other cases of nephritic dropsy are due either to myocardial degeneration or to damage to the capillaries, the dropsy being in fact always extrarenal in origin and the diminished chloride excretion a result and not a cause of the œdema.

[3] The Epidemiology of Bubonic Plague in Great Britain. By William A. Lethem, M C, M D. Journal of State Medicine, November 1923.

[4] Boston Medical and Surgical Journal, June 24th.

[5] Medical Officer, July 3rd.

[1] Cancer—v. Circular 716. Ministry of Health Sept. 16th, 1926. Pp 11. 1d.

Fishberg himself has come to regard the specific gravity of the urine to be almost the most delicate and reliable of all tests of renal efficiency; it is nearly 30 years since Koranyi[4] demonstrated that in uræmic cases the conductivity of the serum remains normal, whereas its freezing-point is greatly lowered, physical facts which to-day are explained by an increase in molecular concentration (i.e., non-protein nitrogen) without gross change in the concentration of electrolytes. Fishberg finds that in all patients with severe renal damage the maximum specific gravity of the urine, even after prolonged deprivation of fluids, seldom reaches 1015 though it is rare for it to fall below 1010, proving that some concentrating power is still left. In order to study this subject a modification of Volhard's technique has been adopted, the patient receives no food or drink after his evening supper, voids his urine in the morning and subsequently supplies hourly specimens for three hours. In a normal man these latter specimens will show a specific gravity approaching 1030, but in no case of uræmia did it reach 1020, and often remained in the region of 1010. The final deduction made by Fishberg is that two stages may be observed in cases of renal hypofunction which he terms those of compensation and decompensation. In the former there is a loss of concentrating power alone which is compensated for by polyuria so that the blood chemistry is undisturbed; in the decompensated stage polyuria either disappears or is insufficient to excrete the waste products, and in consequence the nitrogenous constituents accumulate in the blood giving the typical picture of nitrogen retention. Oliguria, according to this hypothesis, if due to impaired renal function, is but the terminal stage of impaired renal function which affects the excretion of all the urinary constituents. But extrarenal causes of diminished water excretion are far more common, ranging from cardiac failure to the osmotic retention described by Epstein. Such cases can be recognised by the fact that such urine as they do eliminate has a high specific gravity. "Prerenal deviation" is the phrase chosen to describe this phenomenon.

Time alone will decide to what extent Fishberg's views are acceptable, particularly as regards the problems of anasarca, but he has formulated a thesis so lucid and logical as to merit close attention. The work of de Wesselow has pointed consistently in the same direction, and appears to provide strong support for this view.

◆

TERMINAL DISINFECTION

Attention was recently called in our columns[1] to the increasing scepticism with which the modern sanitarian is regarding terminal disinfection of premises as still practised in this country when a case of infectious disease recovers or dies or is removed to hospital. A reasoned statement of the case against terminal disinfection is contained in an article[2] entitled "La Pratique Actuelle des Désinfections Finales," by Prof. Carlos Chagas, Director-General of Public Health in Brazil. Prof. Chagas, who writes as one whose mind is already made up, cites much bacteriological evidence to show that practically all the non-sporing bacteria and protozoa rapidly lose their virulence and power of infection when removed from their natural habitat in the animal host unless carefully nurtured under laboratory conditions. Disinfection is therefore unnecessary, as the virus rapidly succumbs under ordinary domestic conditions. In any case he regards it impracticable to expose all the micro-organisms for a sufficiently long time to the action of chemical solutions or lethal fumes. In Rio de Janeiro disinfection on a large scale was virtually dropped in 1920 without untoward result. Incidentally Prof. Chagas notes the absence of any influence on the tuberculosis curve from radical housing reform carried on in Rio since 1923. He argues that terminal disinfection by health departments diverts public attention from real prophylaxis which takes cognisance of the dangers associated with the patient during the acute phase of his illness, the anomalous and ambulant forms of communicable disease, and the human carrier of infection. He admits that some concession may have to be made for a time to public prejudice by employing a modified form of terminal disinfection, which amounts to little more than an ordinary "spring cleaning." The money saved by discontinuing elaborate technical processes would be well spent on paying health visitors whose function would be to educate those in charge of infectious cases, both as regards the care of the patient and the prevention of the spread of infection. We think that those who agree in the main with Prof. Chagas will nevertheless take note that he quotes only such bacteriological evidence as supports his case. The typhoid bacillus does not always succumb in drinking water within 12 to 14 days, and the search for human carriers can scarcely be so

successful as to permit of all other sources of infection save the actual patients being disregarded His contention that disinfection following plague is valueless because it does not get at the rat and its fleas takes no account of the view expressed by Lethem that the *Pulex irritans* plays a part in the spread of plague in this country[3] Plague bacilli have been demonstrated in pulex by the Indian Plague Commission and by Verjbitski, and the epidemiological circumstances of small outbreaks as instanced by Lethem, are strongly in favour of his thesis "that in this country the first case of an epidemic is infected by a rat flea, usually found in grain or rags," but "that just as plague in rats is spread by rat fleas, so is plague in man in cold climates spread by human fleas, once the disease is started' This sequence of events is worth recalling in connexion with the small outbreak of bubonic plague in Liverpool reported in our last issue The fact that one of the cases—but not the first—was a dock labourer is not in itself sufficient ground for impugning the rat Investigations now being made by the health department with the assistance of the Ministry of Health may throw fresh light on the subject Chagas, again does not even mention the rôle of the infected louse in the propagation of typhus, although terminal disinfection may well be justified in that disease But with these exceptions his argument appears well founded in relation to the prevalent epidemic diseases of civilised communities Judging by a recent leading article in an American medical journal,[4] our attitude to disinfection is regarded as somewhat more conservative than that of the United States and a thorough discussion of opposing views is recommended An incident which occurred in the little town of Godmanchester well illustrates the difficulties which may arise in practice Here the sanitary authority regarded the occurrence of three or four cases of scarlet fever in a school as sufficient reason for its thorough disinfection The county medical officer thought otherwise, and the indignant council passed a unanimous resolution of dissatisfaction with such "dilatory methods" There is much need for education of the public in modern ideas as to the spread of communicable disease

Annotations.

"Ne quid nimis"

EARLY TREATMENT OF CANCER

IN the annual report of the medical officer of health for Willesden, issued not long ago, is a memorandum by Dr W. D Champneys on cancer. indicating what methods of attack have been employed in the fight against this disease elsewhere, and what methods might be employed in the large urban district where he works The introductory pages of this memorandum deal in succession with the nature, distribution, cause, mortality, prevention, diagnosis, and treatment of cancer, they are so lucid and concise that they might well serve as a model for others who are drafting similar pamphlets One word of caution should be added The statement that the recorded mortality from cancer has trebled in the space of two generations, although literally true, is misleading, for in the decade 1851–60, which is taken for comparison, little was known about the diagnosis of cancer. In the final section of the memorandum Dr Champneys outlines a scheme for the control of cancer To this end he would convene meetings of local medical practitioners to discuss the means to be employed and he would get recognised authorities to deliver post-graduate lectures and demonstrations Leaflets and pictorial posters would be distributed to the public, articles inserted in the local press, and popular lectures given But by far the most important measure for securing early diagnosis and treatment is, in the opinion of Dr. Champneys, one that has so far not been tried in this country—namely, the cancer clinic for free diagnosis Such a clinic would be established or maintained by the local authority, provided with X ray equipment and beds for the temporary admission of suspects to enable a thorough examination to be made Diagnosis would be free except for a small charge for a barium meal when administered. It is on this proposal for a free clinic that Dr Champneys will meet with criticism The diagnosis of cancer in its early stage is except in a few selected sites—e g, tongue, skin—impossible without operation, and even after operation and examination of a portion of tumour removed it has recently been recognised that senile involution (in the prostate, for instance) may closely simulate malignant change and be mistaken for such. A free clinic would by no means ensure the certain diagnosis of cancer in the earliest stage when it can be cured In the United States of America, where active propaganda has been carried on for a decade to ensure early diagnosis, the mortality from cancer has not fallen the effect of the propaganda being rather to increase the number of cases detected at an operable stage The taxpayer may also have something to say to the proposal, for. if cancer is not a contagious disease and the sufferer from cancer not a danger to the community. as is the tuberculous or syphilitic there seems no reason why he should pay for the individual who refuses to go to a doctor when he suspects some illness Free diagnosis for cancer would command the support of those who desire free diagnosis of other diseases, in a word, the institution of a State medical service Moreover, life assurance companies would presumably provide means of early diagnosis for their clients, if their actuaries were to advise them that by so doing mortality could be reduced

A far better way of securing early diagnosis is by a campaign designed to induce men and women who are conscious of any tumour sore, or disorder of function to consult their family or insurance practitioner without delay particularly if they are reaching middle-age In a brief Memorandum[1] on Cancer of the Breast, which has been issued from the Ministry of Health in continuation of the memoranda on the same subject which have been appearing during the last three years the dissemination of information on the good results achieved by operation at an early stage is suggested—this to be by means of leaflets, talks, advice from local cancer committees, doctors, health visitors, and social workers Educative counsel directed towards securing effective treatment of earlier conditions which have been shown commonly to precede cancer is also recommended The present Memorandum has relation especially to the results of surgical operation in connexion with breast cancer. and supplements especially the information given in the third Memorandum of the series (THE LANCET. 1924, i, 1074) It incorporates the results of the survey made by Dr. Janet Lane-Claypon with the help of Dr Major Greenwood whereby the previous conclusions in respect to the value of the complete operation at an early stage have been confirmed

A SOURCE OF CHOLERA INFANTUM

THE syndrome of cholera infantum, comprising sudden severe diarrhœa with dehydration and collapse, has been found by many observers to occur in the absence of any ascertainable infection of the gastro-intestinal tract, and of any epidemic source of infection The origin of the disorder has accordingly been referred to as "parenteral," without any definite localisation of the focus concerned ; it has been held likely that this is a variable factor dependent on local and climatic conditions Dr Philip C Jeans and Dr Mark L Floyd[1] have been led by post-mortem examinations of unexplained cases to believe that the focus of infection in cholera infantum is most frequently to be found in the mastoid or paranasal sinuses They do not state, but appear to suggest, that the relation is a constant one. and they are prepared to treat all cases presenting choleraic features in infants by exploration of these sinuses The six cases which they describe furnish a chain of evidence which is certainly very convincing In all six cases pus was found in the antrum or sinus, and those in which drainage was established recovered, while those in which it was not established died Most of the cases occurred not in the summer months when bowel infections are prevalent, but in autumn or winter when the incidence of respiratory diseases is high From the otological standpoint they showed certain peculiar features , the mastoid infections were all bilateral and none of them were evidenced by any of the usual diagnostic signs These observations, in conjunction with the fact that cholera infantum is not a common accompaniment of manifest mastoiditis, suggest that the clinical syndrome described may be produced by some more or less specific infection of the mastoid with characteristics of its own It is for this reason especially to be regretted that the authors' account contains no reference to the bacteriological characters of the infections Information on this point would be of great interest and might yield further indications for prophylaxis and treatment

THE WORLD INCIDENCE OF DISEASE

The Health Organisation of the League of Nations at Geneva has recently issued a large quarto book which gives a summary of the statistics of notifiable diseases in 1925 in 33 European, 34 African, 24 American and 23 Asiatic countries, and in Australasia The data are naturally of varying merit and accuracy , some represent the highest pitch of health statistics which has been reached as yet, some are probably unreliable, at any rate, in detail And if it did nothing else, a publication such as this may be confidently expected to stimulate a progressive improvement in the collection of data, to enlarge the area in which statistics are attempted, and to raise the standard of all the returns to approximate to the best One who turns the pages even casually can see the value of such an accumulation of facts to the serious students of the world's health, especially along two lines There are, on the one hand, the diseases which are liable to be carried from one part of the world to another An agreement has been in operation for many years by which any plague-infected port is notified to everybody, so that ships coming from there may be treated with due respect

The report deals at some length with the prevalence, rise or decline of plague all over the world, and is illustrated with instructive maps Every continent except Australia is more or less infected, from California to Celebes, and from the Black Sea to the Cape and Brazil Serious epidemics in 1925 were limited to Nigeria, Kenya, Uganda, Madagascar, India and Java, and the whole will make anyone wonder what is to be the progress and termination of the pandemic which started out of Southern China 32 years ago The figures for anthrax are useful in the same way Of the countries making returns, Italy and Russia stand out Italy has about ten times as many cases as Germany, and Russia about ten times as many as Italy Within the United Soviet Republics it is far more prevalent in the Caucasus, the Crimea and other parts of the south than in the north, and infection may be specially expected in material coming from the Black Sea ports The practical utility—indeed the practical necessity—of this kind of information needs no further illustration The statistics are equally useful in another direction It comforts us to know that the deaths from tuberculosis in London were 107 per 100,000 people, while they were 291, 280, and 204 in Budapest, Paris, and Vienna But we hope it will stimulate us to better things still to read that the rates were 87 in The Hague and New York, and 83 in Chicago

To know from example what is within the range of achievement is one of the most potent factors in human progress The tale of infant mortality, which is conveniently summarised for 15 great cities since 1881, is the most conspicuous lesson of this Forty years ago six had rates of over 200 and only one was less than 150 , by 1900 Buenos Aires had got down to 93, and eight others were below 150 , in 1925 only five were over 100 and the highest was 126 No one would have thought it possible till confident health officers began to show that it could be done At the end of the volume is an informative table showing what diseases are notifiable in each country, and those who are fond of odds and ends of curious information will find them abundantly throughout

ANTIDIPHTHERITIC MEASURES IN BELGIUM

The prevention of diphtheria is making headway in Belgium, where the small distances and dense population set a problem more easy of solution than in many countries The fact that isolation is enforced less strictly in the case of diphtheria than in other infectious diseases facilitates an estimate of the value of the measures applied, especially in the schools, which are not closed as a routine measure when cases of diphtheria occur in them In Belgium it is not obligatory on practitioners to notify diphtheria, a fee of 5 francs is offered for so doing, but probably many cases elude official notice Diphtheria antitoxin is, however, available free for the use of doctors where there is any chance of the patient being unable otherwise to get it, and apparently advantage is widely taken of this privilege Dr A Bessemans Chief Inspector of Hygiene has recently reported[1] to the International Health Office on the means taken in Belgium to discover susceptible persons and to confer upon them an active immunity The experience of the Belgian Health Service now covers more than 5000 persons who have been subjected to the Schick test, and the figures, classified in age-groups, bring out well the resistance inherent in the child at birth, its gradual loss within the first two or three years of life to be replaced by a progressively increasing resistance acquired from exposure to infection In the age-group 0 to 6 months the percentage of positive reactors was only 36 rising to 76 in the age-group 2–3 years, and gradually falling to 25 in the age-group 17–19 years As elsewhere, a higher percentage of negative reactors was found in the poorer urban quarters, especially where over crowded, a population in which a history of previous sore-throat is relatively common Dr Bessemans's observations on diphtheria carriers are particularly interesting They give no sign of a high degree of natural or acquired immunity, a fact which suggests to him that it is not the mere saprophytic presence of bacilli in the throat which confers immunity, but a definite attack of disease, however slight Dr Bessemans makes the surprising statement that 41 per cent of carriers of true (*vrais*) diphtheria bacilli, as against 44 per cent of the community as a whole, were found to be positive to the Schick test This statement seems to run counter to the whole Schick theory according to which a carrier of *virulent* bacilli cannot be Schick-positive, except possibly for a short space of time The discrepancy has been cleared up by Dr R A O'Brien, who has ascertained by correspondence[2] with Dr Bessemans that the word *vrai* was not intended to imply *virulent*, for Dr Bessemans was not able to test for virulence more than a very small number of the cultures resembling the Klebs-Loffler bacillus obtained from carriers Of the carriers with negative reaction in many of them the negative reaction persisted for weeks or months, leading to the fair inference that a natural immunity does not aid its possessor in getting rid of lurking bacilli Of 71 cases not recognised as carriers, but whose brothers and sisters had been reported to be such, 38 per cent gave a positive reaction, as compared with 11 per cent, for brothers and sisters of actual diphtheria cases, the difference, though small, suggests that the presence of a carrier in the family may have a more powerful immunising effect than the presence of a case of diphtheria Dr Bessemans himself regards the Schick test as in the highest degree trustworthy, for to his knowledge no single one of the 3067 Schick-negative cases contracted diphtheria while at least 11 Schick-positive cases contracted the disease, the diagnosis being confirmed by culture Since the test is simple and has no drawbacks, he recommends its application to the personnel of infectious hospitals and institutions of all kinds His report also contains a note on the value of toxin-antitoxin mixture in conferring immunity on Schick-positive cases, a positive reaction becoming negative within six months in 85 to 90 per cent of inoculated individuals He confirms Zingher's statement that no fear of anaphylactic symptoms need arise from repeated injections of vaccine, for it is always the first which provokes the greatest reaction

TIREDNESS AND FATIGUE

MANY persons, desirous of constantly draining the cup of life's activities to the lees, are often seeking for some wonder-remedy which will prevent tiredness or, at any rate, postpone it until a more convenient season They would disregard Nature's call for rest and turn a deaf ear to the existence of fatigue Tiredness and fatigue are not interchangeable terms, although the two things in most people march closely together Tiredness is a subjective feeling, associated with a desire for rest Fatigue is a condition of diminished capacity for activity and results from activity There are, on the one side, the weary Willies of the world—persons born tired—for whom the ordinary static metabolism of life seems capable of originating feelings of tiredness And, on the other, the acidly active, for whom the most strenuous exercise fails to elicit any desire for rest In practice expenditure of energy to the point of exhaustion is safeguarded, and the utmost a wonder-remedy could do would be to lift the safety-valve and allow more energy to be expended than is physiologically advisable A remedy of this type was reported [1] by Emden in 1921, who announced that during the late war the onset of fatigue had been delayed by administering acid sodium phosphate to German soldiers, to miners, and to animals; support seemed thus forthcoming for those who feel an uplift from the consumption of phosphates A careful and well-planned scheme of research for following up the subject is, however, now reported [2] First, experiments with animals were tried, but abandoned, because no normals or base lines for activity could be obtained Then girls working card-perforating machines were placed under observation, they were being paid by piece-work, of which a record was carefully kept, and presented an ideal group for the study undertaken The phosphate, similarly prepared to that used by Emden and kept below a laxative dose, was taken by 30 girls, while others acted as controls The period observed was Feb 15th to May 31st, the phosphate being given March 13th to April 24th A feeling of well-being was experienced by the phosphate group, probably due to increased elimination of body-wastes, but no detectable increase of muscular efficiency occurred, while the average number of errors was not significantly different The conclusion drawn is that the phosphate created a subjective sensation of less tiredness due to its stimulating action on the intestinal tract, but in no way affected the onset of fatigue And so another wonder-remedy must be relegated to the scrap-heap

THE STUDY OF DYING

DEATH has been considered from many points of view, but it is doubtful if there has ever been any systematic investigation into the events of dying Numerous books describe the death-beds of celebrated men, whilst much of the literature of medicine is devoted to the processes of dissolution and the means of postponing them, yet from the scientific standpoint there is little information available about the final hours of life Writing with much experience of abnormal conditions of the mind, Dr Arthur MacDonald, in our correspondence columns, suggests the collection of such information on a large scale His proposal will be unsympathetic at first sight to those who feel that already there is often too much interference with the dying To many the "systematic study" of the death-bed has a satirical flavour reminiscent of Léon Daudet's "Les Morticoles"—it comes as an addition to the horrors imagined about death Yet the cogency of some of Dr MacDonald's arguments must be admitted It is by no means impossible that the study he suggests might lead to further and wider knowledge which would ease the final hours of those who retain their consciousness to the last Attendance on the dying is a difficult part of a doctor's duties, and one in which he has to rely greatly upon his sympathy and judgment, the young practitioner must inevitably find himself sometimes at a loss, but it ought to be possible to ensure that dying shall generally be easier than it is The subject is not discussed in text-books or lectures It is hard to say whether spreading abroad more accurate knowledge of death would lessen or increase the general fear of physical distress, but medical men—Sir Henry Halford Sir William Osler Prof Hermann Nothnagel and many others—who have written on the subject have usually said that so much dread is by no means justified Some of these opinions are summarised in Dr Parkes Weber's "Aspects of Death and correlated Aspects of Life," which is itself rather a study of the possible mental reactions towards the idea of death in the living than a study of death and its phenomena To those he mentions may be added a short essay by Prof G Perthes, of Tubingen, entitled "Ueber den Tod"

GOGGLES FOR ULTRA-VIOLET THERAPY

FOR short exposure to the ultra-violet rays of the arc or mercury-vapour lamp ordinary spectacle glass is as a rule, sufficient protection, but for operators who may be exposed to the effect of these rays for long periods something more is necessary Various sorts of protective goggles are on the market, but some of them are not to be recommended Thus Mr B D H Watters, of the Middlesex Hospital Physics Department found that a certain grey glass which was being sold for this purpose transmits a considerable portion of the ultra-violet spectrum, with the result that the operator complained of headache and eye-strain after quite a short exposure [1] Inasmuch as it may be necessary to protect the eyes against too strong exposure to the visible rays, a shaded or coloured glass will often be preferred Mr Watters found that a light green tint served the purpose The thickness of the glass, and especially of a concave glass, is a factor which should not be left out of account In order to exclude all the ultra-violet rays a spectroscopic examination of any localisation of the focus concerned ; it has been held likely that this is a variable factor dependent on local and climatic conditions. Dr Philip C Jeans and Dr Mark L Floyd[1] have been led by post-mortem examinations of unexplained cases to believe that the focus of infection in cholera infantum is most frequently to be found in the mastoid or paranasal sinuses They do not state, but appear to suggest, that the relation is a constant one, and they are prepared to treat all cases presenting choleraic features in infants by exploration of these sinuses The six cases which they describe furnish a chain of evidence which is certainly very convincing In all six cases pus was found in the antrum or sinus, and those in which drainage was established recovered, while those in which it was not established died Most of the cases occurred not in the summer months when bowel infections are prevalent, but in autumn or winter when the incidence of respiratory diseases is high From the otological standpoint they showed certain peculiar features , the mastoid infections were all bilateral, and none of them were evidenced by any of the usual diagnostic signs These observations, in conjunction with the fact that cholera infantum is not a common accompaniment of manifest mastoiditis, suggest that the clinical syndrome described may be produced by some more or less specific infection of the mastoid with characteristics of its own It is for this reason especially to be regretted that the authors' account contains no reference to the bacteriological characters of the infections Information on this point would be of great interest and might yield further indications for prophylaxis and treatment

TIREDNESS AND FATIGUE.

MANY persons, desirous of constantly draining the cup of life s activities to the lees are often seeking for some wonder-remedy which will prevent tiredness or at any rate, postpone it until a more convenient season They would disregard Nature's call for rest and turn a deaf ear to the existence of fatigue Tiredness and fatigue are not interchangeable terms, although the two things in most people march closely together Tiredness is a subjective feeling associated with a desire for rest Fatigue is a condition of diminished capacity for activity and results from activity There are on the one side. the weary Willies of the world—persons born tired—for whom the ordinary static metabolism of life seems capable of originating feelings of tiredness And on the other the acidly active, for whom the most strenuous exercise fails to elicit any desire for rest In practice expenditure of energy to the point of exhaustion is safeguarded and the utmost a wonder-remedy could do would be to lift the safety-valve and allow more energy to be expended than is physiologically advisable. A remedy of this type was reported [1] by Emden in 1921 who announced that during the late war the onset of fatigue had been delayed by administering acid sodium phosphate to German soldiers to miners, and to animals : support seemed thus forthcoming for those who feel an uplift from the consumption of phosphates A careful and well-planned scheme of research for following up the subject is however now reported.[2] First, experiments with animals were tried but abandoned, because no normals or base lines for activity could be obtained. Then girls working card-perforating machines were placed under observation : they were being paid by piece-work of which a record was carefully kept, and presented an ideal group for the study undertaken The phosphate. similarly prepared to that used by Emden and kept below a laxative dose, was taken by 30 girls while others acted as controls The period observed was Feb 15th to May 31st. the phosphate being given March 13th to April 24th A feeling of well-being was experienced by the phosphate group, probably due to increased elimination of body-wastes but no detectable increase of muscular efficiency occurred, while the average number of errors was not significantly different The conclusion drawn is that the phosphate created a subjective sensation of less tiredness due to its stimulating action on the intestinal tract, but in no way affected the onset of fatigue And so another wonder-remedy must be relegated to the scrap-heap

THE STUDY OF DYING

DEATH has been considered from many points of view but it is doubtful if there has ever been any systematic investigation into the events of dying Numerous books describe the death-beds of celebrated men whilst much of the literature of medicine is devoted to the processes of dissolution and the means of postponing them ; yet from the scientific standpoint there is little information available about the final hours of life Writing with much experience of abnormal conditions of the mind Dr Arthur MacDonald, in our correspondence columns, suggests the collection of such information on a large scale. His proposal will be unsympathetic at first sight to those who feel that already there is often too much interference with the dying To many the ' systematic study of the death-bed has a satirical flavour reminiscent of Léon Daudet s " Les Morticoles "—it comes as an addition to the horrors imagined about death Yet the cogency of some of Dr MacDonald s arguments must be admitted It is by no means impossible that the study he suggests might lead to further and wider knowledge which would ease the final hours of those who retain their consciousness to the last Attendance on the dying is a difficult part of a doctor s duties and one in which he has to rely greatly upon his sympathy and judgment ; the young practitioner must inevitably find himself sometimes at a loss. but it ought to be possible to ensure that dying shall generally be easier than it is The subject is not discussed in text-books or lectures It is hard to say whether spreading abroad more accurate knowledge of death would lessen or increase the general fear of physical distress. but medical men—Sir Henry Halford Sir William Osler. Prof. Hermann Nothnagel and many others—who have written on the subject have usually said that so much dread is by no means justified Some of these opinions are summarised in Dr Parkes Weber s ' Aspects of Death and correlated Aspects of Life ' which is itself rather a study of the possible mental reactions towards the idea of death in the living than a study of death and its phenomena To those he mentions may be added a short essay by Prof G. Perthes of Tubingen entitled ' Ueber den Tod '

GOGGLES FOR ULTRA-VIOLET THERAPY

FOR short exposure to the ultra-violet rays of the arc or mercury-vapour lamp ordinary spectacle glass is as a rule sufficient protection : but for operators who may be exposed to the effect of these rays for long periods something more is necessary Various sorts of protective goggles are on the market but some of them are not to be recommended Thus Mr B D. H Watters, of the Middlesex Hospital Physics Department. found that a certain grey glass which was being sold for this purpose transmits a considerable portion of the ultra-violet spectrum with the result that the operator complained of headache and eye-strain after quite a short exposure [1] Inasmuch as it may be necessary to protect the eyes against too strong exposure to the visible rays a shaded or coloured glass will often be preferred Mr Watters found that a light green tint served the purpose. The thickness of the glass. and especially of a concave glass is a factor which should not be left out of account. In order to exclude all the ultra-violet rays a spectroscopic examination of any

unknown glass is essential *According to a chart* published in a paper by Sir Arnold Lawson[2] Crookes's glass is constant in its absorption almost irrespective of the tint, Crookes A and Crookes B being practically *identical in their absorptive* power as far as the ultra-violet rays are concerned, but they only absorb rays of a shorter wave-length than about 360 $\mu\mu$. London smoked glass No 4 has a similar effect Fieuzal glass No 2 cuts off all the ultra-violet rays Amber does not For the *operator it* is desirable to secure the maximum amount of visible radiation with a minimum transmission of any rays with a wave-length shorter than 400 $\mu\mu$. For the patient the choice need not be so restricted, partly on account of the short time during which he is exposed to the action of the rays and partly because in his case there is no objection to cutting off some of the visible light The manufacturers of Arcos glass claim for it a total absorption of ultra-violet, as well as greatly reduced transmission of heat rays, and they supply an easily sterilisable form of goggles

MEDICINE AT KHARTOUM

THE School of Medicine at Khartoum, founded as a memorial to Lord Kitchener, is designed to meet the need for native doctors in a rapidly developing country Native doctors are needed to work under British doctors at the larger hospitals, to take sole charge of smaller hospitals, and to engage in field work against the endemic diseases—malaria, bilharziasis, ankylostomiasis, yaws, and syphilis—which are interfering with the increase of the population and diminishing its efficiency The school was opened in February, 1924, by the late Sir Lee Stack and work was commenced with a first-year class of ten students selected from young men who had completed their course of training at the Gordon College A further class of eight students was admitted in January, 1925 The report, which has just been issued, tells of the work completed by the end of that year. Photographs show the handsome buildings, the lay-out of the laboratories, dissecting room, lecture room, and library, and students at work in them The school stands in three and a half acres of land lying on the western side of the main avenue running north from the railway station to the Palace, which faces the Blue Nile, rebuilt on the foundations of Gordon's Palace. On the other side of the avenue is the Khartoum Civil Hospital Adjacent to the hospital and fronting the medical school new research laboratories are being erected, and provision is being made in these laboratories for the teaching of pathology A school hostel, under construction 200 metres away, will afford immediate accommodation for 40 students and admit of *extension* if called for later The house of the medical registrar responsible for the work and conduct of the students is situated in the school enclosure The curriculum covers a period of four years The first *year is* devoted to the preliminary *sciences*, the second to anatomy, physiology, and histology, the third to medicine, surgery, and pathology; and the fourth year continues the third-year subjects and includes also lectures and demonstrations in public health, midwifery and gynæcology, and a brief course in forensic medicine Clinical teaching is given in the well-equipped Civil Hospital, which has 100 beds and a large out-patient department The hospital at Omdurman, a town of 80,000 inhabitants separated from Khartoum by the White Nile, affords additional material for clinical demonstrations Importance is attached to the teaching of public health, for which the three towns with their combined population of 130,000 provide ample scope With the exception of the registrar, all the teachers belong to the Government medical and scientific staff · thus the medical and surgical teaching is given by the physician and the surgeon of the Khartoum and Omdurman hospitals, public health teaching by the medical officer of health of these towns, pathological teaching by the Wellcome Research Laboratories. As a consequence the school budget is maintained at a figure which would otherwise be quite impossible, the total expenditure for the year 1925 with the first and second-year classes under training was only £2447 When the third- and fourth-year classes come under training the expenditure will increase in proportion and additional sources of income will have to be found The progress made during these first two years points clearly to success in the future, and we hope that no question of financial stringency will be allowed to hinder a work so important to the material progress of the country and to the welfare of its people

UNIVERSITY OF EDINBURGH: THE D T.M & H. AND D P.H.

THE Students' Number of THE LANCET was published this year at a time when the regulations for the degrees of B Sc and D Sc in Public Health at the University of Edinburgh were under consideration, but the regulations for the diplomas in Tropical Medicine and Hygiene and in Public Health are in order, as are the regulations for the diploma in Psychiatry. Candidates for the D T M & H diploma *must be graduates in medicine and* surgery of the University or hold corresponding degrees or qualifications from other sources, and the full course of instruction is given during the autumn term, *beginning therefore in October* The diploma of the University in Public Health is granted to candidates of a similar standing, and the course is divided into two parts, for which examinations are held twice annually, in March and July for Part I, and in October and December for Part II. The course, which extends over 12 calendar months, begins in October, and provision is made by the University for instruction in all the subjects, while candidates must study for at least two of the three terms in the University Detailed particulars regarding these diplomas, which are contained in full in the University Calendar, may be obtained from the Dean of the Faculty of Medicine at the University This notice was accidentally omitted from the Students' Number of THE LANCET

THE COOMBE HOSPITAL.

IN anticipation of the Coombe Hospital centenary celebrations, which have been held in Dublin this week, Dr T P. C Kirkpatrick has contributed to the September number of the *Irish Journal of Medical Science* a sketch of the history of the *hospital* In 1821 the Meath Hospital moved from the house it had occupied in the Coombe for just half a century to its present site in Long-lane The vacant house was taken by Dr Kirby, head of one of the private medical schools, who established 50 beds in it and used it for the clinical instruction of his students Some years later the question arose of providing accommodation for maternity cases on the south side of the *city*, as patients suffered hardship in making the journey to the Rotunda Hospital, which was then the only maternity institution in Dublin In 1826 *it* was arranged to take one ward *in* Kirby's Hospital for maternity work, and thus the Coombe Hospital began its special work. In 1829 the surgical part of the hospital was closed and the institution became the Coombe Lying-in Hospital, with Dr Richard Reed Gregory as its first master From the first the hospital paid much attention to teaching, and issued certificates to the pupils who attended its *practice* These certificates were accepted by the Royal Colleges of Surgeons in Ireland, of England, and of Edinburgh, as well as by the medical boards of the Navy, *Army*, and Indian Medical Services When, some years later the Rotunda Hospital began to issue diplomas in midwifery which purported to be qualifications to practise, the Coombe followed suit, and acute controversy arose between the two institutions, the Rotunda holding that as the

---

[2] British Journal of Ophthalmology, 1925

Coombe had no charter it had no right to issue diplomas It was not till 30 years later, in 1867, that the hospital succeeded in obtaining a Royal Charter. In the meantime both diplomas had lost much of their value by the passing of the Medical Act of 1858 While the teaching work of the Coombe Hospital was increasing in reputation the buildings were falling into decay, but fortunately good friends were found in successive members of the Guinness family, and between 1868 and 1877 it was rebuilt at their expense. Various improvements have since been made and in the hands of recent masters the hospital has done much to enhance the reputation of Dublin as a teaching centre for obstetrics

The Services.

ROYAL NAVAL MEDICAL SERVICE

Surg Capt. W L. Martin to be Surg Rear-Admiral

The following appointments are notified —Surg Rear-Admirals: W. L. Martin to *Egmont* and for R N. Hospl Malta (on joining); and R St. G S Bond to *Vivid* for R.N Hospl. Plymouth. Surg Capts.: A R Thomas to *Vivid* for R.N Hospl. Plymouth, and R. W. B Hall to *President* for service in Medical Dept Admiralty and as Deputy Medical Director-General Surg Comdrs. A R. Fisher to *President* for three months post-graduate course, E. L. Atkinson to *Pembroke* for R N Barracks. Chatham, temp: F G. H R. Black to *Vivid* for R.N Barracks Devonport and for specialist duties. J D Bangay to *Victory* for R.N Barracks Portsmouth L. MacEwan to *Dolphin* as Senior Medical Officer Submarines: C T Baxter to *President* for Royal Victoria Yard Deptford for survey of stores. J M Hayes to *Egmont*; A J Tozer to *Ramillies*; J T Skelton to *Princess Margaret* and as ophthalmic specialist, temp.; R. F MacMahon to *Pembroke* for R M Infirmary, Chatham, and F. Cock to *Egmont* for R N Hospl Malta as ophthalmic specialist (on relief) Surg Lt.-Comdrs: W J Colbourne, N A. H. Barlow, J. E. Clark, W. A. Jolliffe, N B de M Greenstreet, A W Cocking and J. S Elliot to *President* for five months course of instruction; R. W. Nesbitt to *Victory* for R.M Infirmary, Eastney; E Heffernan to *President* for Royal Victoria Yard, Deptford for survey of stores: and T Gwynne-Jones to *Sandhurst*. Surg Lt-Comdrs (D): J. T. Wood to *Excellent*; J F. Pace to *Ganges*; and T. A. B Corless to *Pembroke* for R.N Hospl, Chatham. Surg Comdr (D): H. M Meek to *Pembroke* for R N Barracks Chatham. Surg Lts.: J Hamilton to *Pembroke* for R.N Hospl Chatham temp Surg. and M. Barton (short service) transferred to the permanent list.

ROYAL ARMY MEDICAL CORPS

The undermentioned Capts. to be Majs.: J. Higgins, E B Marsh C Armstrong (Prov) J. A. L. Wilson (Prov), J H. Fletcher and D G Evans (Prov)

Capt E N P. Martland retires receiving a gratuity

The undermentioned to be Lts. (on prob) F M. Collins and J A. Chapel

The undermentioned to be temp Lts.: R A. M Humphrey and W. A. Kerr.

ARMY DENTAL CORPS.

The undermentioned temp Capts. Dental Surgs. Gen List, to be Capts: J L. Gibson, F. W. Burke, S H. Bannerman, J W Vasey, A. H Kay D A. McGeorge, Allen Rhodes, N F Smith, J. L. Newton and D J. Muil

The undermentioned temp Lts Dental Surgs. Gen. List to be Lts.: B Abbott, G A. Ballantyne, F. H R. Davey F F. Anslow, W. B Purnell F. S S Whiter R. A Roth, D C Blyth C E Day F G Arnold, R. H N Osmond, W McAndrew, and B J Swyer

ROYAL AIR FORCE

Flying Officer F. L. White is granted a permanent commission in this rank.

The undermentioned are granted short service commissions as Flying Officers for three years on the active list E A. Rice and C W Coffey

Squadron Leader C L. Colbran is promoted to the rank of Wing Commander (Dental) on promotion to Lt.-Col in the Army Dental Corps.

INDIAN MEDICAL SERVICE

The King has approved the relinquishment of his temporary commission by Lt Behari Lal Chopra.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions

CLXXXIX.—THE MEDICAL TREATMENT OF CHRONIC DIARRHŒA.

II.—MANAGEMENT OF THE CASE.*

Gastrogenous Diarrhœa.

ANY likely cause of a true chronic gastritis (e.g. alcoholic excess gross oral sepsis excessive tea drinking) should be appropriately dealt with. Soups and condiments and hurrying over meals should be forbidden Acid hydrochlor. dil. (B.P.) ♏ xx. to xxx. in a tumbler of orangeade or sugar and water, taken as a beverage during each of the three main meals, causes a prompt and complete cessation of the symptom in the majority of cases Even smaller doses may be effective. Ultimately it may be possible to dispense with the acid or to rely on one or two doses in the course of the day. Where the acid is given for its antiseptic action as well as to control the diarrhœa (as in cases of pernicious anæmia) much larger doses up to a drachm or more, t.i.d., should be employed

Chronic Ulcerative Colitis and Chronic Bacillary Dysentery

The treatment of these conditions may be considered under the headings of specific (or serum) therapy and non-specific therapy The patient should be kept in bed throughout the period of intensive treatment and until the stools are formed. Specific measures should only be employed in cases which have been fully investigated, and steps should be taken to discover whether the patient has been sensitised by previous administration of serum. In cases in which cultural investigation of the stools or serological tests confirm a suspicion of infection with *B Flexner* or Shiga polyvalent anti-dysentery serum should be given in full doses, and as Hurst[1] has shown, good results may also follow the same treatment in a certain proportion of cases of "non-specific" ulcerative colitis The serum should be given by the intravenous route starting with a dose of 30 or 40 c cm. and, unless reactions are severe, followed by injections given daily or every other day, and increasing up to 60 or 80 c cm. until 200 to 250 c cm. have been given in all. The only drawback to serum therapy is its expense, but this is outweighed by other considerations. In successful cases there will already be an improvement in the patient's general condition at the end of a week or 14 days with a reduction in the number of stools Within a fortnight or three weeks sigmoidoscopy may show commencing healing in the mucosal lesions of the lower bowel The diet at first should be lacto-farinaceous with fruit juice, jellies &c. It should be of ample caloric value, and include liberal fluids No food containing vegetable residue or other indigestible fibre should be allowed. Careful attention should be paid to oral hygiene. Powdered charcoal (½ oz.) with arrowroot twice a day helps to diminish intestinal flatulence and pain. The colon should be irrigated once a day in the early stages with quantities increasing gradually from ½ to 1½ pints of a tannic acid solution (½ to 2 gr. to the oz) or with weak silver solutions or normal saline, the fluid being introduced with the patient in the knee-elbow position or on the back with the hips well raised and after the bowels have been moved A soft rubber tube and funnel should be employed the tube being introduced not further than 3 to 4 inches and the fluid run in very slowly with only slight pressure (not more than 1 foot) The patient should be encouraged to retain the injection a little longer each day up to half an hour Iron should be given for the anæmia A mixture originally suggested by Wedgwood[2] for use in typhoid fever and containing tr ferri perchlor ♏ x–xx with liquor hydrarg perchlor ʒss three times a day has found several advocates. When the stools have become formed, as they may do somewhat abruptly in successful cases, liquid paraffin should at once be given to obviate constipation and consequent mechanical damage to the newly healed mucosa Symptomatic improvement under treatment should be controlled by sigmoidoscopic examinations

---

* An article in this series by Dr. Pyle on Chronic Diarrhœa Investigation of the Case, appeared in THE LANCET last week.

[1] A. F Hurst. Guy's Hospital Reports, 1921, lxxi., 26.

Chronic Amœbic Dysentery

The effect of a course of 12 subcutaneous or intramuscular injections of emetine hydrochloride (gr 1 daily) on symptoms and sigmoidoscopic appearances should be tried, particularly if the diagnosis has not previously been made In cases which have previously had much treatment with emetine the results are less satisfactory Emetine bismuth iodide (gr. iii in salol-coated tabloids) given daily for 12 days and, more recently, stovarsol gr iv daily for 12 or 14 days have proved of value in resistant cases Manson-Bahr[3] has also reported favourably on yatren both by mouth and irrigation For more detailed descriptions of the treatment of chronic amœbic dysentery reference should be made to works on tropical diseases Repeated courses of treatment are often necessary

Spurious Rectal and Colonic Diarrhœa.

The treatment of the spurious rectal and colonic diarrhœas is the treatment of constipation It should include strict regularity, ample fluids, a diet liberal in fresh and stewed fruit and green vegetables, avoidance of purgatives, employment of lubricant preparations such as liquid paraffin, and in cases with colonic spasm small doses of belladonna Enemata in gradually diminishing quantity may be required in the earlier stages to re-educate the lower bowel, and in old persons it may occasionally be necessary to break up a fæcal accumulation in the rectum The "diarrhœa" usually described as occurring "in attacks" and so bitterly complained of by sufferers from so-called muco-membranous colitis is usually made worse by (1) bismuth, chalk, and opium, (2) purgatives, and (3) douche treatment Visits to spas for douche treatment should be discouraged The diet should be as for a case of constipation, only seedy fruits and very fibrous vegetables being excluded Lubricant preparations and belladonna and bromides may be employed Four to six ounces of liquid paraffin injected into the bowel at bedtime and retained over night, a pad being worn, often gives relief in the more troublesome cases Vigorous psychotherapy, instructions to the patient not to inspect her stools, emphatic assurance that the frequent actions are due to irritation of the bowel by scybala rather than to inflammation by disease, that the mucous discharge is nature's response to such irritation, and, finally, that there is no true colitis present may contribute to a successful handling of these difficult cases

Tabes Mesenterica and Cœliac Disease

The usual hygienic measures, including proper rest. open air and sunshine, and controlled by temperature and weight records, must be employed for adequate periods in cases of tabes mesenterica with diarrhœa In the milder cases a reasonable restriction of the fat intake is the only other treatment required In the more serious cases with bulky stools, butter cream, and the visible fat of meat should be excluded altogether, and the milk should be skimmed Unless there is an associated ulceration of the small bowel these measures alone may bring about a prompt cessation of the diarrhœa, although the stools will remain bulky In children especially it is important to provide fresh food elements in other forms such as fruit juice Gull[4] was the first to point out how irrational it was to give fatty foods and cod-liver oil in cases in which large quantities of fat were being voided in the stools

The treatment of *cœliac disease* is carried out on closely similar lines, and is described in detail by R Miller in THE LANCET, 1923 ii, 1099

Sprue

Among the many treatments which have been employed in sprue the milk treatment is probably least liable to failure Milk is given in large quantities advancing up to six or even eight pints in the day, and at first no other form of food is employed When the stools have become formed and the weight is gaining, easily assimilable carbohydrates are added and later protein foods Much has been made in recent times of the calcium and parathyroid treatment suggested by Scott[5] This treatment has found many advocates, but among physicians with wide tropical experience opinions remain divided For a fuller discussion of the treatment of sprue reference should be made to text-books on tropical diseases

Pancreatic Diarrhœa

The most important indication is to cut out fat from the dietary as completely as possible, as the fat indigestion is probably the main cause of the diarrhœa If there is no glycosuria liberal carbohydrate feeding may be instituted Ripe bananas are a valuable addition to the dietary, and glucose, cane-sugar or lactose given in large quantities in lemonade and other fluids may help to maintain the weight. Of the protein foods those requiring the least trituration and digestion should be favoured It is difficult to obtain reliable evidence as to the influence of the enzyme substances, but one of the preparations of pancreatin should be given with each of the three main meals

Other Forms

For *nervous diarrhœa* a codeine pill ¼ or ⅓ gr taken occasionally before those events which have been found to precipitate the symptom may act effectively by controlling peristalsis and so help to restore confidence Common-sense hygiene, proper mastication, instructions with regard to obtaining a complete evacuation each morning, and simple explanations concerning the mode of perpetuation of such symptoms by apprehension are also helpful During times of mental stress a bromide mixture should be given

In *diarrhœa due to excessive consumption of carbohydrate* it is only necessary to remodel the dietary and to insist on more exercise

Diarrhœa following Gastro-jejunostomy—In the more innocent form due to a too-patent stoma, dry meals, a short rest in the recumbent position after meals, and (if achlorhydria and no ulceration be present) small doses of acid and pepsin are generally effective.

Conclusion

Of the varieties of chronic diarrhœa discussed above gastrogenous diarrhœa is the most common and incidentally the most tractable Diarrhœa due to rectal or colonic carcinoma is also common, but too frequently attributed in the early stages to simple ulcerative colitis The fatty diarrhœas and diarrhœa following gastro-jejunostomy are rare An attempt has been made to review the various types in the order of frequency in which they are encountered in hospital and consulting practice in this country

Special Articles.

A STUDY OF SCARLET FEVER

EPIDEMIOLOGY AND PROPHYLAXIS

EVER-INCREASING attention is being given to the epidemiology of zymotic diseases A report prepared by Sir George Buchanan and Dr Allan C Parsons, which has just appeared embodies the results of an inquiry carried out under the auspices of the Comite de l Office Internationale d Hygiene Publique into the comparative prevalence of scarlet fever, its characteristics, and the measures adopted for its prevention in various parts of the world This report is essentially a summary of replies to a questionnaire sent out to some 30 countries, and appears in the *Bulletin* of the Office Internationale for June and July Information was desired on four specific points (1) the methods by which an estimation of the incidence of scarlet fever was arrived at including notification, hospital statistics, and death certificates, (2) the special characteristics of the epidemics—prevalence, seasonal incidence periodicity, morbidity and mortality rates, virulence, and any factors looked upon as of importance in the spread of infection, such as delayed notification or diagnosis, carriers, schools, and the like, (3) general methods of prophylaxis and of treatment; and (4) methods of terminal disinfection

Notification

The sources of information in the various countries are fairly comparable Notification of scarlet fever is compulsory in most of the places in which it is endemic, in several countries the local health authority is notified by the physicians, by the hospitals and by the education authorities, and the only countries in which a fee appears to be paid to the notifying physician are England and Wales, Belgium and Algeria Deaths are registered in nearly all the countries in which the disease is notifiable The prevalence of scarlet fever is not easy to ascertain, but it appears that the countries situated in the north-west and south-east of Europe are chiefly affected The seasonal incidence is fairly constant, definite periodicity has usually been noted, although this varies a good deal in different countries and in different parts of the same country The incidence rate per 100,000 of the population ranges from 224 in Northern Ireland and 218 in England and Wales down to 12 in South Africa, 9 in Greece, and 7 in Czecho-Slovakia It is probable, however, that fewer cases escape notification in Great Britain than in most of the other countries on the list, and in any case the value of these figures as also of the mortality rate depends largely upon the completeness of census and death certification With regard to the virulence of the disease, it would appear that in England, Norway, Sweden and Holland the type has become progressively milder of recent years, although due allowance has to be made for the fact that larger numbers of notified cases are now admitted to the hospitals In other countries, especially in South-Eastern Europe, the disease appears to be more virulent in type than in former years.

Infection and Susceptibility

Most of those who replied to the questionnaire were clearly of the opinion that the spread of scarlet fever is almost entirely a personal question—i e, that each fresh case is directly infected by some other person who may be either obviously suffering from scarlet fever, or convalescent from an attack, or else suffering from a mild, abortive, or unrecognised infection The existence of perfectly healthy 'carriers" is frankly doubted by most of those who replied on this point Nasal, pharyngeal, or aural discharges are looked upon in many countries as the agents chiefly responsible for the spread of infection Much work has been done, chiefly in America, on the results of the Dick test for ascertaining the susceptibility of a given subject to scarlet fever A number of tables and charts prepared by Dr Abraham Zingher and by the Dicks themselves are reproduced in this report, showing the high percentage (90 7) of negative reactions in the case of those who have already had an attack of scarlet fever, and the comparatively high percentage (75 4) of positive reactions in those who have never been infected In another series of cases the test was applied to patients during an attack of the disease, the percentage of positive reactions being 98 during the first five days of the illness, 20 after the sixth day, and 8 7 during convalescence The use of scarlet fever antitoxin as a preventive measure is warmly advocated by the Dicks, who have shown the direct correlation that exists between the quantity of toxin administered and the immunity obtained They claim that their toxin can be safely administered in doses large enough to confer complete immunity, such immunity being attained in the course of two weeks and lasting for at least 18 months As a curative measure the use of serum from convalescents is being tried with success in various countries, including Stockholm, Poland, and Czecho-Slovakia Isolation hospital treatment is the rule in several of the countries, although not in all opinions also differing as to the respective merits of barrier, cubicle, or ward nursing

Quarantine.

An interesting point is the varying procedure as to isolation In the United States an average of four to six weeks is usually required, in Stockholm six weeks, in Holland, five, in Italy and in Australia, four weeks The same divergence exists with regard to desquamation In Norway no notice is taken of desquamation of the feet, nor, in Sweden, of any desquamation after the sixth week In many parts of Holland the state of the skin is not considered as any criterion of infection, certain authorities not regarding the skin as infectious at any period of the disease unless it has been contaminated by discharges. In Italy, Manchuria, and Bulgaria, on the other hand, the patient is usually considered infectious until desquamation is complete A large variety of methods of disinfection are in use in the various countries These are usually applied in the terminal stage, but it is of particular interest to note that in many countries in which sanitary science is making rapid headway there is a distinct tendency to give up the traditional terminal disinfection of sick rooms in favour of bedside or current disinfection of the patient This is the case in Norway, Sweden, Bulgaria, Denmark, Holland, Canada, and a few of the United States of America although in most of these countries terminal disinfection has not yet been entirely abolished As Dr Parsons points out, the newer method is practically an extension of the bed or "barrier" system of isolation, both being based on the theory that only the patient and the articles recently contaminated by him are infectious

Epidemiology

Another recent study on the epidemiology of scarlet fever is that by Dr Alton S Pope[1] The data for this paper were collected by Dr C V Chapin, who for 40 years has kept individual histories of all cases of scarlet fever reported in the American city of Providence In all, the number of cases investigated has been 17,625, the writer explaining that "By the intensive study of the disease over a long period in one locality, and the correlation of the findings with extensive researches, the attempt has been made to add something to the natural history of scarlet fever" The points made by Dr Pope include the following First as to age distribution Approximately 75 per cent of all cases occur under 10 and 90 per cent under 15 years the greatest incidence being at six years The highest mortality *in scarlet* fever occurs in the third year of life Although there has been no appreciable change in the recorded morbidity of scarlet fever in Providence during the past 40 years, there has been a relative shifting of mortality from the lower to the higher age-groups, the mortality rates themselves also having fallen during this period from approximately 40 to 2 per 100,000 On the evidence available, the decrease in mortality appears to be due to a decrease in the malignancy of the disease rather than to any special measures adopted for its control Attack rates in Providence show a slight excess among males up to the sixth year of life, and at all ages above 7 a marked excess among females The month of greatest incidence for scarlet fever is usually January, the minimum incidence in July or August in all but three years out of 40 No evidence of periodicity in the incidence could be found in the Providence figures.

Among 22,000 cases of scarlet fever, 271 were recorded as second attacks Dr Pope believes this to be an under-estimate of the percentage of recurrence of scarlet fever in the individual, although the fact that only one-seventh as many cases were recorded among those who previously had the disease as among the general population shows that one attack does confer a relative immunity A marked preponderance of females in the higher age-groups among recurrences is evidence that infection with scarlet fever depends to a great extent upon intimacy of contact

A recent U S Public Health Report (Vol XLI, No. 24), gives the results of Dick tests made on different groups of school-children in Fairfax county and in Washington The groups of rural and suburban school-children were found to give a higher percentage of positive reactions than did the children in city institutions. A similar result was found in the case of children who had already suffered from scarlet fever, the difference being explained either by a difference in degree and frequency of exposure in city and rural children, or by the suggestion that different strains of scarlet fever streptococci may produce different toxins A relatively greater immunity was found to exist in males than in females, this difference being found to increase with age When two or more children from one family were tested there was a tendency for the reactions on the different children to agree. When disagreement occurred, the younger children were more often positive and the older children more often negative

GENERAL PRACTITIONER SERVICE.

ITS RANGE UNDER THE INSURANCE ACTS

THE insurance medical service is at the present time, as Sir George Newman writes in his Report,[1] a service of general medical practitioners Each practitioner, by his agreement with the insurance committee, has contracted to give to his insured patients "all proper and necessary medical services other than those involving the application of special skill and experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess," and it is provided in the terms of service for practitioners that in "determining whether a particular service is a service involving the application of such special skill and experience as aforesaid, regard is to be had to the question whether services of the kind are or are not usually undertaken by general practitioners practising in the area in which the question arose"

The medical benefit regulations lay down a procedure for determining whether a given service falls within the content of medical benefit If a practitioner thinks that a service which he has either already performed, or is about to perform is outside the scope of his obligations, he is required to supply the insurance committee with particulars of the service on a form furnished by the committee The form is then sent to the local medical committee, who are asked to state whether in their opinion the service as described by the practitioner is one that involved "the application of special skill and experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess" In the regulations operative prior to 1924 the question was formulated as to whether the service was one which "could consistently with the best interests of the patient be properly undertaken by a general practitioner of ordinary professional competence and skill" The opinion of the local medical committee is considered by the insurance committee, and if the two committees fail to agree the matter must be referred by the Ministry of Health to referees, whose decision is final If the two committees agree the Ministry may, in the exercise of its discretion, refer the matter to referees. The regulations require that the referees, who are nominated by the Ministry, shall be two medical practitioners and one barrister-at-law or solicitor in actual practice, and they have power to determine their own procedure

Many cases have arisen for decision and lists of the rulings given since 1920 were set out in Vol III of the Reports of Inquiries and Appeals under the N H I Medical Benefit Regulations,[2] and may be summarised here

Some Cases not Referred to Referees

In the following instances the local medical and insurance committees held that in the particular circumstances the operation or other service *was* of a kind which could properly be undertaken by a general practitioner of ordinary professional competence and skill

(1) Treatment of fracture of both bones of leg and dislocation of ankle
(2) Treatment of gonorrhœa by irrigation and medicine.
(3) Opening and scraping abscess of thigh
(4) Curetting of uterus
(5) Suppurative mastitis opening and breaking down all pockets and inserting rubber drainage-tubes
(6) Opening and draining an ischio-rectal abscess
(7) Advanced cirrhosis of liver with very severe ascites and general dropsy, local anæsthetic injected Incision made, cannula and trocar inserted, drainage-tube fitted to cannula
(8) Operation for fissure in ano
(9) Removal of facial sebaceous cyst
(10) Deep abscess of neck due to liquefaction of glands; incision made, sinus forceps inserted and creamy material evacuated Syringed out with iodine
(11) Dislocation of left elbow, reduction under chloroform.
(12) Ophthalmoscopic examination for occipital headache.
(13) Removal of epithelioma of lower lip

In another group of cases the committees agreed that in the particular circumstances the operation or other service *was not* of a kind which could properly be undertaken by a general practitioner of ordinary professional competence and skill

(1) Removal by dissection of Bartholin's gland
(2) Passage of Eustachian catheter
(3) Operation for hæmorrhoids
(4) Examination of eyes by retinoscopy
(5) Colpo-perineorrhaphy and stitching the cervix.
(6) Gastro-jejunostomy
(7) Removal of varicose veins
(8) Intravenous administration of novarsenobillon
(9) Enucleation of eyeball
(10) Radical cure of left inguinal hernia
(11) Operation for suppurating fibroid with local pelvic peritonitis
(12) Removal of tuberculous glands in neck
(13) Extreme genu valgum in both legs—osteotomy of femora
(14) Excision of multiple fistulæ in ano (horseshoe variety)
(15) Removal of internal semilunar cartilage of left knee
(16) X ray treatment for recurrent carcinoma of axillary glands
(17) Application of radiant heat and ionisation
(18) Complete tonsillectomy—curetting nasopharynx
(19) Removal of large sebaceous cyst from right side of neck.

---

[1] On the State of the Public Health Annual Report of the Chief Medical Officer of the Ministry of Health for 1925 H M Stationery Office 3s

[2] H M Stationery Office 1924 3s

(20) Dissecting out cyst over mastoid.
(21) Removal of epithelioma of axilla.
(22) Cauterisation of nose and tonsillectomy.
(23) Excision of hypertrophied turbinate bones in nose and excision of tonsils and adenoids.
(24) Excising and suturing bladder sinus.
(25) *Peritomy.*
(26) Resection of intestine. (Paul's operation.)
(27) Amputation of toes.
(28) Removal of appendix.
(29) Removal of nasal polypi.
(30) Operation for chronic gastric ulcer—carcinomatous.
(31) General anæsthetic for tonsillectomy and gastric enterostomy.

Some Cases Referred to Referees

Other cases were referred to referees, and the decision on those in Group I was that in the particular circumstances the service was one which could consistently with the best interests of the patient properly be undertaken by a general practitioner of ordinary professional competence and skill, while in the cases included in Group II the decision was to the contrary effect.

Group I.

(1) Removal of fibroma adenoma of breast.
(2) Removal of needle from foot.
(3) Operation for cellulitis.
(4) Removal of papillomatous tumour from back.
(5) Removal of cyst from neighbourhood of knee-joint.
(6) Taking blood (venous) as a preliminary to the Wassermann test for syphilis.

Group II.

(1) Removal of thrombosed and varicose veins in leg.
(2) Operation for atresia oris uteri interni with retroflexion.
(3) Amputation of arm below elbow.
(4) Removal of epulis from between teeth.
(5) Removal of polypus from rectum.
(6) Operation for hæmorrhoids.

Special Skill and Experience

When an insurance practitioner has actually performed an operation or other service which he contends is outside his insurance obligation on the ground that it involved the application of special skill and experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess, the onus is thrown upon him to establish that he himself does possess such special skill and experience. By his contention he implicitly states that his professional colleagues in the area as a class do not possess the special skill and experience which he claims that he does possess, and before his claim can be admitted the regulations provide that he must prove:—

(*a*) that he has held hospital or other appointments affording special opportunities for acquiring special skill and experience of the kind required for the performance of the service rendered, and has had actual recent practice in performing the service rendered or services of a similar character, or

(*b*) that he has had special academic or post-graduate study of a subject which comprises the service rendered, and has had actual recent practice as aforesaid, or

(*c*) that he is generally recognised by other practitioners in the area as having special proficiency and experience in a subject which comprises the service rendered.

The question of determining the range of the insurance practitioner's obligations is one of great importance. If the performance of a certain operation is held to be not one of those services which the practitioner has in virtue of his agreement with the insurance committee contracted to render when necessary to his insured patients, he is entitled to charge the patient a fee for the service. The question, therefore, is one that affects the statutory rights of the insured population, and it was obviously necessary that a procedure should be devised for dealing fairly, effectively, and expeditiously with cases in which it is doubted whether a given service is or is not within the scope of a practitioner's insurance obligation. The procedure described in the preceding paragraphs has been in operation for the past 13 years, and Sir George Newman considers that it has stood the test of time. "I think it is true to say," he adds, "that insurance practitioners as a body are not disposed to take a narrow view of the range of their obligations, and it is known that there are practitioners who habitually and without charge render to their insured patients services which, if the question were raised, would probably be held to be outside the scope of medical benefit."

SMOKE ABATEMENT AND HEALTH: CONFERENCE AND EXHIBITION

BIRMINGHAM, SEPT. 6TH–18TH.

BOTH the householder and the manufacturer who visit the Smoke Abatement Exhibition which is drawing to a close, at the Bingley Hall, Birmingham, can find there a very practical display of all the principal established methods of efficiently abating smoke. There is little that is new except in detail, save for a development in the design of a domestic grate constructed for burning gas coke. At the Conference of the Smoke Abatement League of Great Britain held in connexion with the exhibition last week it was generally accepted that whatever the future may hold in store, the only existing solid smokeless fuel suitable for domestic use and available in considerable quantities is the coke produced from gas-works. Nevertheless gas coke has admitted drawbacks; as Dr. Margaret Fishenden, of the Fuel Research Board, remarked in a paper on the Outlook for Smokeless Domestic Heating, difficulty of ignition and relatively low combustibility have tended to make coke unpopular with the housewife. These disadvantages are due partly to the low volatile content of gas coke and partly to its inherent physical characteristics; "but they are frequently accentuated," she added, "by the presence of large amounts of moisture and ash and by the practice of selling coke ungraded—i.e., not separated according to size." The future use of coke for open fires depends therefore partly upon improved production and grading, improvements to which gas undertakings have of late given much more attention. But the type of grate in which it is consumed can also assist by making ignition and combustion easier and by reducing the amount of ash liable to be sent into the room. It is in these respects that the new "Glow-Worm" open coke fire designed by Dr. J. S. Owens is important and worth describing fully.

A Practical Open Coke Fire Grate

In ordinary open fires the combustion of the fuel is from bottom to top. Ash is formed and needs to drop downwards into the ash-pan, but the air for combustion rising up through the fuel tends to keep the ash in the fire, and when the fire is poked throws the fine ash out into the room. With the "Glow-Worm" fire combustion is from back to front through a wedge-shaped fire-basket. Ash in falling is carried through into the ash-pan, and however vigorously the fire may be poked, no ash or dust comes out into the room. To promote the fullest possible amount of radiant heat the ash-pan is pushed backward, when the whole of the fire exposed to view will become a glowing incandescent mass. The addition of new fuel does not obscure the pleasing appearance of this incandescent fuel or in any way interfere with the amount of radiant heat sent out into the room. By pulling the ash-pan forward a certain amount of air instead of passing through the fire will go under the fire and up the flue, in addition to which air constantly passes under the canopy of the fire and thereby ventilates the room. As the flue at the back of the stove terminates at a point higher than the mouth of the canopy, a true injector effect takes place. The fire itself has been constructed with a tapered back so that it will partly fit into the average existing coal grate. In this way the projection into the hearth is reduced to the minimum and a pleasing appearance is obtained. The consumption of coke is from 1 to 1½ lb. per hour, and the cost, therefore, of using this fire is considerably less than the average coal fire with its attendant dust and trouble There is no need at any time to lift out the remainder of the previous day's fuel Fresh fuel can be added on top of the cinders at the bottom of the grate, and ignition is rendered simple and quick by the provision of a gas-lighter

Ventilation and Heating

The papers and discussions at the Conference, like the stands at the exhibition, mainly retold what was already known—not indeed to the bulk of fuel-users, but to the scientists and experts Sir John Robertson and Dr Leonard Hill dealt effectively with the value of sunlight and with ventilation and heating, and both argued strongly that there is no justification for the continued use of raw coal on its present enormous scale In Dr Hill's words it is bad policy to "put off the demand for abolition of smoke pollution on the plea of waiting for the economic production of a smokeless fuel better than coke and gas The modern gas fire has been perfected so as to give a maximum of radiant energy including visible red rays which penetrate the skin and the tissues to some depth" It was also, he said, a fairly efficient ventilator, especially where a second opening into the flue was provided, as in the best designs, so as to raise the total ventilation of a small shut-up room to some 3000 cubic feet an hour But the radiant energy of a gas fire, he added, is so great that a window can and should always be kept open He laid considerable stress on the error both of overheating, a common mistake in using gas fires, and of monotonous heating, there was a definite advantage in the variations in the heat emitted by coal fires, and though this could be easily obtained with gas, people tended to make too little use of the control which the gas taps afforded

Dr J S Owens underlined the emphasis laid on ventilation In estimating the "efficiency" of heating appliances, the function of the appliance must be clearly understood, you cannot, he said, relate input to output unless you know what sort of output you want It so happens that ventilation is a function generally left to heating appliances, and it is misleading to talk of an appliance being highly efficient when it fulfils the heating function only There was also good sense in Dr Owens's point that it is not necessarily sound to be always seeking to render new fuels suitable for use in appliances designed for some other fuel, it may be better policy to adapt appliances to fuels than fuels to appliances

The Domestic Chimney

Much light on the practicability of domestic smoke abatement was supplied in a paper on Municipal Housing Schemes by Mr E D Simon and Miss M FitzGerald The Smoke Abatement League circulated to local authorities a questionnaire designed to elicit what steps, if any, they had taken to reduce or abolish smoke from their own houses, and what were the results in the opinion of both authority and tenants The answers, summarised in the paper, clearly showed that domestic smoke abatement was practically a new idea to some authorities In a very fair number of housing schemes, however, provision had been made for smokeless heating and cooking with the exception of one coal fire, and in some cases all-gas and all-electric houses had been tried After making allowance for the natural dislike of change, even for the better the evidence justified the conclusion that a far wider use of smokeless methods would be acceptable and economic even in houses occupied by people of limited means The Conference endorsed the view that the Government in its Smoke Abatement Bill was quite needlessly overcautious in refusing to deal with the domestic chimney A purely permissive clause was required, enabling local authorities to make regulations with regard to cooking and heating arrangements in *new* dwelling-houses, with a view to reducing smoke

Mr Raymond Unwin and Mr Pointon Taylor, Chief Architect and Chief Assistant Architect respectively to the Ministry of Health, while defending the Government's caution, set forth in their paper on "Clean Air and Clean Houses" the possibilities of smoke abatement in an encouraging way which seemed hardly consistent

Further Steps.

Papers were also contributed on the subject of industrial smoke, and a preliminary step was taken to bring about the formation of voluntary associations of manufacturers to study in cooperation and apply individually means of eliminating the inefficiency and waste which their present smoke production represents. A more comprehensive suggestion was also thrown out that the delay between the admitted establishment of economic remedies for smoke and their adoption by domestic and industrial fuel-users might be reduced if a national smoke abatement movement were brought into being, embracing all the smoke abatement efforts now carried on too much in isolation At any rate the Conference made clear the slowness with which people put into practice even smokeless methods that are known to pay, apart from their value as such

Attendance at the exhibition has been disappointingly small But at present it is not apparent whence the funds are to be drawn for a campaign on a scale which would attract adequate notice

---

MEDICINE AND THE LAW

Hospital Collection Frauds

MENTION was made in this column a few weeks ago of sentences passed upon a group of defendants who had been conspiring to obtain charitable contributions by fraud Their method was to represent themselves as an organisation engaged in collecting money in aid of hospitals, and they obtained considerable sums from audiences at cinematograph theatres, being sometimes allowed to address the audiences from the stage An associate of these defendants pleaded "Guilty" on Sept 8th at the Central Criminal Court to a charge of conspiring to obtain charitable contributions by fraud, and was sentenced to nine months imprisonment in the second division He would have been tried and sentenced with the defendants in the previous proceedings had he not disappeared while on bail awaiting trial In a country where the hospitals rely so largely upon voluntary subscriptions this particularly mean fraud seems to require specially vigorous measures It is perhaps hopeless to expect the charitable public, though often imposed upon, to examine the credentials of every person who invites contributions for charitable objects But a great deal can be done by local, if not general, restrictions upon the abuse of flag-days, and upon unauthorised collection in places of public resort By-laws should be elaborated, if necessary, and every locality should see that its inhabitants are protected The bench will no doubt bear in mind, too, the desirability of passing exemplary sentences

Poisoning Cases Immediate Treatment at Hospitals

There are few practitioners who have not had experience of the manifestations of disappointment of persons who wish for the immediate treatment of a patient at a juncture when every moment of professional time is already occupied with the treatment of others The same disappointment must often occur where a hospital is asked to give facilities or accommodation when neither are available At an inquest on Sept 10th the Hackney coroner (Dr Edwin Smith) commented adversely upon the action of a doctor at the German Hospital at Dalston, who had omitted to treat a woman suffering from lysol poisoning The woman was found lying unconscious upon the floor of her kitchen, having apparently swallowed poison She was taken to the German Hospital, but, as no bed was available, she was removed to the Metropolitan Hospital, where she died an hour later. The coroner's point was that first-aid should have been rendered and that for this purpose it was unnecessary to wait till the patient could be put to bed The resident at the German Hospital was asked if he did not think it would have been better to have gone down and looked at the patient before sending her away to another hospital He did not agree · he said it would have taken some time to administer treatment and he was not in a position to admit her to his hospital It appeared from his further evidence that the German Hospital was not equipped with a poison cupboard with stomach-pumps antidotes and emetics in readiness for prompt use, and that it would have taken time to collect apparatus and drugs The coroner in recording a verdict of "Suicide while of unsound mind ' took the view that while treatment would not have saved life in this instance. the hospital should have been prepared to meet such an emergency We note that in the Medical Directory this hospital is described as ' for . . all cases of emergency.'

Patient Declining to Remain in Hospital

An incident of a converse character, occurring on the same day illustrates the reluctance of some patients to be admitted to hospital A woman was knocked down by a motor-car and was taken in an ambulance to St. George s Hospital There she was examined by a doctor who advised her to remain She declined to remain and signed a document to the effect that she had left of her own accord and contrary to the doctor s advice Five days later she was found dead at her flat The post-mortem examination showed that the deceased a woman of 60. had a fissured fracture at the base of the skull a fracture of such a nature that it could hardly be diagnosed during life She had also four ribs fractured The divisional police surgeon Dr Percy J. Edmunds giving evidence in the Westminster coroner s court expressed the opinion that the deceased had lain in bed for some time but that, owing to the gradual oozing of blood in the brain she had begun to feel faint and probably got up to summon assistance when she fell and died The coroner s jury returned a verdict of ' Accidental death '

BERLIN

(FROM OUR OWN CORRESPONDENT)

Epidemic of Gastro-intestinal Catarrh.

IN certain districts of the city of Hanover an epidemic of gastro-intestinal catarrh has occurred fortunately without fatal issue up to the time of writing [1] It has been ascertained by the Hygienic Institute of Hanover that the cause of the disease was a contamination of the drinking water Although the organisms of enteric fever. dysentery or cholera were not present, the percentage of germs in the water from one of the waterworks was found to have considerably increased The epidemic which had affected a large number of the people in the district which is supplied from this source, has now been stamped out and officials of the Health Office state that the water is now safe for drinking purposes without being boiled They are of opinion that the inundations of this summer had caused germs from the surface of the soil to penetrate into the deeper strata whence the water is derived , moreover a deficiency in the drains due to the floods had allowed the waste water from a tar factory to find its way to the water-works

Birth-rate in Germany and in France

At a recent meeting of the Berlin Society for Public Health the birth-rate in Germany was discussed by Prof Grotjahn He stated that formerly the birth-rate had exceeded the number of deaths. so that the population showed a constant increase and Germany became overcrowded This state of things has changed during the last 20 years. At present the number of deaths is certainly smaller than that of the births: this is. however. attributed to the fact that during the war so many people were killed. and immediately afterwards, during the inflation, underfeeding caused the premature death of others Now that normal conditions have been restored the death-rate is expected to show an increase whilst the birth-rate will diminish The decrease of the birth-rate is believed to be due to the indiscriminate use of contraceptive drugs and appliances a factor common to all nations of the West ; in Slavonic countries an enormous number of births still take place By statistical researches it has been ascertained that to maintain the number of the population—not to increase it—there must be three children for every marriage and as every marriage cannot produce that number there must naturally be families with more children In France there is a law according to which families of small financial means receive support from the municipality on behalf of every child born after the second They moreover enjoy other privileges Germany has done nothing in this direction Prof Grotjahn pointed out that it is erroneous to believe that the decrease of the birth-rate is a remedy for unemployment. The example of France shows on the contrary. that the decrease of the birth-rate in a country induces foreign workmen to come to seek work there The state of things in Germany is the more undesirable, as in France the decrease of births has been nearly stopped for several years whilst in Germany it is still growing steadily In Germany in 1900 35 births were registered for each 1000 inhabitants : in 1924. only 20 4 In France the birth-rate was only 21 3 in 1900 . but scarcely less—19 3—in 1924 The speaker (Prof Grotjahn) advised the Government to adopt and to improve upon the French system of support of families having many children

Articles in the Medical Press

Seventy-eight editors of German medical periodicals, including the leading medical journals have collectively approached the heads of university clinics and other scientific institutions asking them to insist on the reduction to a reasonable size of articles submitted for publication by their assistants. They state that they can no longer afford to give as much space as before the war to lengthy communications and point out that when the MSS for publication are shortened in the editorial office undesirable controversy may ensue Heads of clinics and scientific institutes are therefore asked to use their authority in supervising articles issued by their juniors and to induce them to submit MSS in a more concentrated form Articles of minor importance when too long, must inevitably be refused The editors point out that this step has been taken only in the interest of maintaining the high standard of their journals

Statistics of Hospitals in Prussia

In 1924 the number of hospitals clinics, and infirmaries in Prussia was 2195. of which 1816 were public institutions The number of institutions has decreased by 134 since 1913. but the number of beds has increased being 205 516 against 177 184 in 1913 For each 10.000 inhabitants 54 9 beds are now available against 42 5 before the war The number of hospital patients in 1924 was 1 606 178, against 1,534 209 in 1913 Of these 88 836 died. giving a death-rate of 5 5 per cent., against a death-rate of 6 1 in 1923 and 5 6 in 1913 The relation of the deaths in hospital to the general death-rate was. in 1924, 193 5 to 10 000, in 1921 177 8 and in 1913. only 136 7 This relative increase of the deaths in hospital is ascribed to the fact that membership to a sick club which has to cover the expenses of a hospital stay having become compulsory for a much greater percentage of the population. in consequence many more patients than formerly are conveyed to hospital when ill

---

[1] Fatal cases have since been reported in the press in which the outbreak has generally been described as one of typhoid fever —ED L.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH

The following are some of the health statistics of three English and two Scottish counties (landward areas) for 1925 .—

Name of county	Estimated mid year population (R G)	Birth rate	Death-rates per 1000 of the population: All causes	Tuberculosis	Cancer	Resp diseases with influenza	Heart disease	Death-rates per 1000 births: Infant mortality.	Maternal mort from childbirth
Warwickshire .	361,700	18 5	11 1	0 91	1 31	2 0	1 5	62	5 1
Hertfordshire	346,600	15 8	10 4	0 84	1 49	1 7	1 6	47	3 3
Northamptonshire	215,300	16 2	11 7	0 97	1 44	1 7	1 6	57	3 2
Dunbartonshire	54,449	19 3	12 3	0 88	1 49	2 0	1 7	72	4 7
Roxburghshire	19,819	15 7	14 1	0 85*	1 61	2 3	2 7	60	9 6

* Average for 3 years 1923–25, including burghal area

Warwickshire.

Dr A. Hamilton Wood reports that the infant death-rate of 56 in the urban districts compares very favourably with the 66 recorded in the rural districts There were 22 deaths from diarrhœa in the rural as compared with only 4 in the urban, which may be the result of the better facilities in the urban districts for infant welfare work The population of the urban district is 157,500, and of the rural 204,200 Sixty-seven cases of small-pox were notified in the county with no deaths Diphtheria, unlike scarlet fever, maintains its position as a fatal infectious disease The case fatality among the 542 cases notified in 1925 was 6 4 per cent Dr Wood is of opinion that this case-rate would be reduced if the early administration of antitoxin were more generally adopted The public also need to be educated to seek medical advice early in all cases of sore-throat when diphtheria is known to be present in the district Of the 8 cases of enteric fever notified 4 were of the mild or paratyphoid type (Two deaths occurred in males of 25 and 45 years respectively There were 46 notifications of encephalitis lethargica with 26 deaths Dr Wood thinks that several adjoining counties should combine to establish an institution for the treatment of the survivors from this disease There was a widespread epidemic of influenza in the first quarter of the year, which led to the closure of 114 schools , the deaths numbered 138

After a conference with all the local authorities in the county it was decided that the County Council should administer the Milk Act of 1915, and the veterinary surgeons under the Diseases of Animals Acts have been appointed for this purpose The examination of milk for tubercle was only just begun at the close of the year During the current financial year the Council has authorised the examination of 50 samples for tubercle bacilli, which does not seem a large number. The treatment of pulmonary tuberculosis by sanocrysin was begun at the Memorial Sanatorium during the summer So far the results are encouraging The County Council have issued instructions with regard to the examination of diphtheria swabs which are expected to effect an economy without interfering with efficiency Convalescents are only to be swabbed if there are clinical signs Convalescents are not to be readmitted to school until two or three weeks after the end of the illness on the certificate of the district medical officer Virulence tests will only be carried out on the authority of the county medical officer of health Swabs among contacts are only to be taken from those showing clinical signs Emphasis is laid on the dictum of the Medical Research Council that the diagnosis of diphtheria is the province of the clinician, who cannot place any of the responsibility on the shoulders of the bacteriologist

Dr Wood is impressed with the small number of women who present themselves for treatment at the V D centres, and he is convinced that the only solution is treatment in the doctor's private surgery At the five V D centres only 40 new female cases were treated, as against 162 men The grant previously made by the County Council to the nursing associations for the training of midwives is to be modified so as to become a grant towards the appointment of midwives to work in the county The new cases who attended at the four antenatal clinics during 1925 numbered only 218, while the total births were 6677 The midwives attended 4890 births and sent for medical help in 885 cases Arrangements have been made during the year for the orthopædic treatment of children under 5 years of age at the Dunsmoor Clinic, Coventry, maintained by the Coventry Cripples' Guild There are now 34 infant welfare centres, all run by voluntary committees working in close association with the County Council The two county maternity homes have fulfilled a much-felt want, as there are still many young married couples who have to live in rooms The Rugby Home admitted 89 cases and the Warwick Home 34, and, in addition, 108 extern cases were attended by the midwives of the Warwick Home Of the 30 cases of ophthalmia notified, one resulted in total blindness and another in impaired vision

Hertfordshire

Dr. H Hyslop Thomson gives particulars of the home conditions of 389 patients suffering from tuberculosis The conditions are described as good in 60 5 per cent , indifferent in 28 6 per cent , and bad in 10 9 per cent In the case of 68 per cent there were 2 or less persons per bedroom, in 21 7 per cent there were 3 persons, in 8 5 per cent 4, and in 1 8 per cent over 4

The conditions of the ex-Service men come out best, of the insured persons second best, and of the uninsured worst The information obtained "indicates the existence of overcrowding and emphasises the urgent need for the provision of additional houses" There is an absence of adequate accommodation in certified institutions, more especially for low grade and complicated cases of mental defect The difficulties met with show the importance and urgency of the steps which have been taken to provide a certified institution and training colony There were 15 notifications of encephalitis lethargica 14 being from the urban districts Of the 9 deaths 8 occurred in the urban districts The chief advance made during the year in the maternity and child welfare scheme had been the establishment of 4 antenatal clinics, which were attended by 269 expectant mothers, the number of births in the administrative county being 5481

Maternal deaths from puerperal sepsis continue at about the same level In Hertfordshire Dr Thomson suggests that the condition is due to auto-infection rather than to infection introduced from without Inquiries with regard to the feeding of infants indicate that at the age of 6 months 66 per cent are entirely breast-fed, 17 per cent are partly breast-fed, and 17 per cent entirely bottle-fed The report of Miss Harrington, the county health visitor, inspector of midwives and superintendent of nurses shows that 2699 of the births were attended by midwives alone, almost exactly half the total births It is further stated that among the births attended by midwives alone only 15 of the infants died before the tenth day The Registrar-General's report shows 94 infantile deaths in the county within the first week. If the information on which Miss Harrington's statements are founded is complete, it follows that the proportion of deaths was five or six times higher in the remaining cases.

In previous reports Dr. Thomson has complained of the dumping of house refuse in the county by outside authorities. He now reports that since the precautions suggested by the Ministry of Health have been carried out the objectionable features of these refuse dumps have been considerably lessened, and that the covering of railway wagons conveying refuse has also improved matters. The regulations for the grading of milk are cited and also the provisions of the new Milk Act and of the Tuberculosis Order of 1925, but it is not stated that any action has been taken with respect to these measures. The state of the private slaughter-houses in the county is still far from satisfactory, and there is need for the erection of central abattoirs. Thirteen samples of apples were examined for arsenic. 4 were free, 7 showed traces negligible in amount, while in the case of 2 the amounts of arsenic were 1/50 and 1/60 of a grain respectively per lb. of apples.

Northamptonshire

Dr. L. Meredith Davies acknowledges the help of his predecessor, Dr. Paget (who resigned on March 21st, 1926) in the preparation of the report. In November 1918 Dr. Paget reported on the question of maternity hospital provision. In July 1922 a maternity home was opened in the borough of Northampton, which was partially subsidised by the County Council. During 1925 the whole subject of maternal mortality was further considered in conjunction with a special committee of the medical profession in the county. The medical delegates expressed themselves as in favour of the establishment of antenatal clinics and hospitals for complicated maternity cases on condition that the services of a specialist obstetrician and gynæcologist were available at such clinics and hospitals. It was decided to approach the boards of the Northampton and Kettering general hospitals. As regards the carrying out of the new milk legislation it has been decided that samples shall be taken by the inspectors appointed under the Food and Drugs Act, that the veterinary work shall be done by the inspectors appointed under the Diseases of Animals Acts, and that arrangements be made if possible, with the Northampton General Hospital for the necessary bacteriological work. There were 17 cases of ophthalmia neonatorum, 13 notified and 4 unnotified. In 2 cases there were opacities, one of the left eye and one of both eyes, and an operation was necessary in both cases to secure any vision. Both of these were doctor's cases and unattended by midwives in any capacity. There were 13 cases of puerperal fever with 5 deaths, 1 being a midwife's case, 2 being attended by midwives as monthly nurses and 2 unattended by midwives in any capacity. In spite of reminders issued for two years in succession, the midwives do not always notify cases of artificial feeding. During 1925 29 of these cases were unnotified and Dr. Davies thinks that the reasons for abandoning natural feeding are frequently not valid.

Five patients suffering from lupus were treated at the out-patient department of the London Hospital by Finsen light and arc light baths. Three were cured and two were under treatment at the end of the year. 187 cases of small-pox were notified with 2 deaths. An advance was marked in 1925 as regards the erection of dwellings by private enterprise, 511 were completed as compared with 366 in the previous year. There were also 223 in course of erection at the close of the year. The houses erected by local authorities numbered 106 as compared with 89 in 1924 and in addition there were 216 houses in course of erection. During the years 1921–25 1634 houses were completed by local authorities and 1279 by private enterprise. During the same period closing or demolition orders were made in respect of 125 houses. The county analyst, Mr. E. W. Voelcker, reports that under the food orders of 1919 shredded suet had to contain at least 80 per cent. of fat, and that now in some cases over 30 per cent. of rice-flour is added, the fat being less than 65 per cent. He thinks this excessive amount of "diluent" should be controlled by law.

Dunbartonshire

Dr. Thomas Lauder Thomson reports that in March 1925 an arrangement was made with the Glasgow Corporation whereby tuberculous "suspects" could be examined by X rays at Ruchill Hospital. Of the 22 cases examined 4 were positive, 1 doubtful, and 10 negative. Four were referred to the tuberculosis officer and in 3 the examination was repeated. Although these examinations do not give conclusive results in all cases Dr. Thomson thinks they are valuable as confirmation in doubtful cases. Most of the farmers are doing their best to carry out the by-laws framed for securing better accommodation for seasonal workers. A milk vendor was fined during the year for breach of the Milk and Dairies (Amendment) Act, 1922. He was selling milk from a barrow in one of the populous areas in the county and the barrow had inscribed on it "Milk free from tuberculuous" and in large letters "Smith's pasteurised milk." There was also a picture of a churn with "Grade A" printed on it. This vendor had no licence for any grade of milk and disregarded warnings. The school clinics have been opened for all children irrespective of age, and this enables children to be sent from the child welfare centres for the treatment of diseases of the ear, nose, throat, eyes and teeth, and also for the treatment of ringworm. The fever hospital service has been improved by coöperative arrangements between the three hospitals, so that if one hospital becomes overcrowded patients can be transferred to another.

Roxburghshire

Dr. M. J. Oliver shows that when the last two quinquennia are compared the infant mortality-rate has been reduced from 81 to 65. This reduction would no doubt have been attributed to a welfare scheme if the county had had one; some of the credit Dr. Oliver assigns to the local nursing association. During the year a known typhoid carrier died in Kelso Hospital. Since she was first ill in Northumberland in October, 1913, she had been the cause of 11 cases of typhoid fever in Roxburghshire. The Kelso district committee did their best to protect the community without undue hardship to the sufferer by providing her a home with necessary conveniences at the public cost, but, in spite of this, infection was more than once communicated to other people. She underwent an operation in Glasgow in 1923 for the purpose of getting rid of the infection. The operation was apparently successful, but she died from an intercurrent affection during the long course of bacteriological testing needed to make sure that she was free from infection. Dr. Oliver records that a few more cases of puerperal fever have been notified than usual, but that this probably does not indicate any real increase in numbers. Many medical practitioners find a difficulty in determining what cases should be notified under this "antiquated term." Cases notified are generally in the practices of senior members of the profession whose reputation can stand the possible imputation.

Dr. G. F. B. Page in reporting on the tuberculosis scheme says we must dispose of the time-worn myth, "the light job in the open-air." No such job exists at a living wage. It is best for the patient to return to his original work unless it is one of half a dozen intrinsically unhealthy occupations. Dr. Page thinks that we ought to realise that light treatment of tuberculosis is in an experimental stage and that harm may be done by its injudicious use. The forms of tuberculosis which benefit most are those of exudative type.

THE STUDY OF DEATH IN MAN

To the Editor of The Lancet

Sir,—In order to encourage a systematic and scientific study of the dying hour, I would suggest that medical societies pass some such resolution as —

Resolved That the Medical Society of the favours the scientific and systematic study of the physiology and psychology of death in man, and requests its members to make such studies in every case of death when there is opportunity

It is a curious fact that as yet there seems to have been no systematic and scientific study of human death There have been more or less sporadic efforts to make such investigations in exceptional and interesting pathological cases But the regular order, so to speak, or the average manner of death is not known Some of the main reasons for such study are —

1 To gain trustworthy and general knowledge of what most often takes place in the dying hour, including details

2 To learn the manner of death for different diseases and the per cent of those conscious and unconscious

3 To find in what per cent of cases there is severe pain, slight pain, and no pain

4 To note details in exceptional and special cases and the causes of these phenomena and the length of dying time

5 To determine the characteristics and differences in dying between infants, children, adolescents, adults before middle life, during middle life, in old age, and from 80 to 100 years of age, including points under numbers 2, 3, and 4 for their ages

6 To present eventually a general picture of the dying time, based upon a sufficient number of observations, and with instruments of precision when possible

7 That with such knowledge the treatment of patients during the dying time may be more humane and delicately done

8 That in cases that are liable to be painful, proper precautions may be taken in advance, so that pain may be avoided or greatly lessened

9 That finally the knowledge of the dying time may be so increased that physical death will cease to be feared or dreaded by all persons, since through such knowledge pain may be practically eliminated and death may be made easy, gentle, and placid

I am myself seeking opportunity to make observation on cases of death, and I would consider it a great favour if any physician who makes observations and studies of cases during the dying time will send me a copy of his notes and results, for which due credit will be given when sufficient data are received to justify publication

I am, Sir, yours faithfully,

The Congressional Apartments, 100 E Capitol-street, Washington, D C

CHENOPODIUM FOR ANKYLOSTOMIASIS

To the Editor of The Lancet

Sir,—Mr Paget's recent paper on the determination of the ascaridol content of oil of chenopodium, to which Messrs Burroughs Wellcome and Co call courteous attention in your issue of Sept 4th, shows that the constants laid down for that oil in the U S P are valueless unless the oil is a genuine one, since they can be reproduced by skilful adulteration, and, moreover, that the means advised in that Pharmacopœia for determining the ascaridol content are not effective in such an adulterated oil With a genuine oil, however, the old methods of estimating ascaridol, especially the specific gravity test, are shown to be fairly or actually accurate Accordingly if one may assume, as seems reasonable, that the bulk of the oil used generally in anthelmintic work has been genuine, the findings of Mr Paget's careful investigation authorise little misgiving in the continued use of the mass of information which has been accumulated in the tropics on the administration and effects of oil of chenopodium

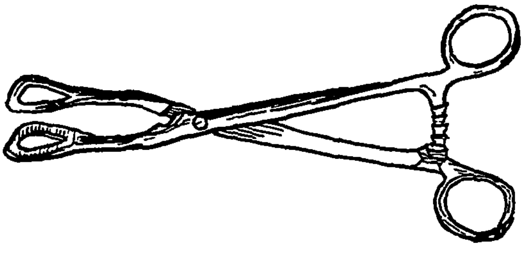
The letter under consideration raises a second point of equal practical importance Burroughs Wellcome and Co have produced an oil of chenopodium having an ascaridol content of 90 per cent and upwards In 1 2 c cm of this oil there is as much ascaridol as in about 1 8 c cm of an ordinary sample Put otherwise, to give 1 2 c cm of this preparation is equivalent to giving 1 8 c cm of an ordinary sample, while a dose of 1 5 c cm is equivalent to 2 25 c cm In order to administer the ordinary dose of ascaridol the dose of this particular oil must be only 0 8 c cm, a vital matter seeing how slight must sometimes be the margin between safety and anxiety in the case of ascaridol, equally with that of the other anthelmintics of which we have present knowledge

I am, Sir, yours faithfully,
Ealing, W, Sept 10th, 1926 Clayton Lane.

A PLEA FOR THE PERMANENT ABOLISHMENT OF THE "LINGUOTRITE"

To the Editor of The Lancet.

Sir,—The "linguotrite" or tongue-crusher, is a brutal instrument which is still far too frequently found in the anæsthetist's tray of our hospitals up and down the country I am not implying that any professional anæsthetist would think of applying such an instrument to the tongue of his patient, but in the heat of the moment, when it suddenly becomes necessary to draw the tongue forward, as long as this contraption is at hand it will continue to be used by those whose duty it is to administer anæsthetics For weeks after its application the tongue is swollen and painful The bruising and subsequent inflammation constitutes a clinical entity—linguotritic glossitis I have observed several examples of this condition, which may be said to be the only omission from that masterpiece of surgical monographs, Butlin's "Diseases of the Tongue" The remedy is simple The linguotrite should be once and for all relegated to the dust-bin, and a pair of rational tongue forceps substituted



I am, Sir, yours faithfully,
Sept 10th, 1926 Hamilton Bailey

THE PATHOLOGICAL SERVICE OF THE GENERAL HOSPITAL

To the Editor of The Lancet

Sir,—I entirely agree with Dr Powell White The pathologist has quite enough to put up with in competition with commercial, greater hospital, and university laboratories without having his own hospital interfering with his private work As to paying a stipend and receiving rent (which would be practically impossible to assess) the hospital would be giving with one hand and receiving with the other, the pathologist remaining a paid servant, giving hospital cases precedence and possibly losing private work

I think the only satisfactory solution has been found here The hospital provides the laboratory and its equipment, the pathologist is a member of the honorary medical staff, and he practises as a specialist consultant in the strictest sense He also does a good deal of public health work, being paid according to an agreed scale of fees for each item He is his own master, he does not give preference to any case, hospital or private, he takes them as they come, on their necessity He certainly has to work very hard, and consulting specialist practice in the country is not brilliantly remunerative, but he retains his self-respect and makes enough to live on with the ordinary decencies of life, although he cannot afford a car, which is not a professional necessity in his case

JUSTICE FOR HOMER BOSTWICK

To the Editor of THE LANCET

SIR,—There has recently come into my hands an example of literary piracy of an extremely interesting type which, for historical and other reasons, I should like to comment upon The pirate was a Dr Homer Bostwick, who practised in New York between 1840 and 1870 The victims were Philippe Ricord, the famous French syphilologist, and his London pupil, William Acton

Briefly the facts are as follows In 1848 there appeared a volume, " A Complete Practical Work on the Nature and Treatment of Venereal Diseases, and other Affections of the Genito-Urinary Organs of the Male and Female," by Homer Bostwick, M D New York Burgess Stringer and Co, 1848 Bostwick sent a copy to THE LANCET for review, inscribed "Thomas Wakley J Henry Bennett With the respects of the author " It is this copy which is now in my possession The inscription, I think, is in the author's handwriting, because Bennet's name is wrongly spelt Why a single copy should have been sent between two men is not very obvious Possibly it was economy Henry Bennet was obstetric physician to the Royal Free Hospital at the time, wrote for many years on THE LANCET staff, and was a friend of the Wakley family The copy contains a series of caustic pencilled notes, in the margins, on which the review, to be presently commented upon, was afterwards built Apparently this is the only copy of the work in London, and, I think, it must have been sent to Acton as a curiosity of piracy after Wakley had finished with it Acton's library passed to Sir Alfred Cooper, formerly senior surgeon to the London Lock Hospital, and from Cooper's library it, with other books of Acton, came to me Probably after the castigation which it received in THE LANCET the book fell dead on the market And yet, in spite of everything said, and truly said, against it, re-reading it now, nearly 80 years after, with an unbiased mind, I have been much impressed by certain opinions expressed and statements made, which, unorthodox in their day, have since been proved correct Bostwick may have been a pirate, but he was also an acute clinician, and it is in the hope that some reader may be able to supply details about this forgotten author that I wish to resurrect the matter

The review appeared in THE LANCET of 1849, vol i, p 401 It begins —

> "We doubt, brother Jonathan, if it was a smart trick in you to send us this book for review So long as it occupied the shelves of your publisher, in Broadway, or was read in the repudiating States, the deception might have been undiscovered but with us your fine plumage cannot conceal your daw's carcass, for your book contains nothing good but what you have pillaged from this side of the Atlantic "

Imagine starting a review thus in these days! But at that time there was considerable irritation in England against the United States, because certain individual States had borrowed money for railway and other public services, and when the interest became due had repudiated responsibility, leaving the bond-holders high and dry But why visit the sins of defaulting States on an unfortunate medical writer? Again I quote from the review —

> "In looking over the American annals of literature, we must all be painfully struck with the injustice of United States men in seizing our best surgical works, and reprinting them, as soon as published, with what are called Notes by Dr This, or Observations by Mr That Doubtless it is easier to steal a book than write one, even though it contain trash, but we very much question if this dishonest system is likely to protect or foster native talent, any more than it will improve national morals, or promote international respect and brotherly feeling "

Here the reviewer is giving vent to his indignation as a writer upon seeing literary property stolen before his eyes, and even now the United States remain the only great nation refusing to recognise international copyright, even though large sums of American money reach English authors

Having thus pilloried the States, and the publishers' morals, the reviewer returns to Bostwick thus —

> "It was, however, left for Dr Bostwick to outvie any of his countrymen in injustice to authors on this side of the Atlantic In a large, handsome quarto, with coloured plates, woodcuts, and bold type, he has, under his own name, published a book on Venereal Diseases, which, almost from beginning to end, has been plundered from the works of M Ricord and Mr Acton "

The great feature of the work, the profusion of coloured plates, is thus dealt with —

> "'Some of the drawings,'" Bostwick says, "'I have borrowed from the great work of Ricord, others from Acton and some I have taken directly from life'"

On this it is commented —

> "Whatever his 'returns' may be, his 'borrowings' have been pretty considerable We have looked into the works in question, and believe we can trace every coloured plate or woodcut (about 70 in number), except one, to English or French treatises But our transatlantic daw, not content with this wholesale borrowing, as he calls it, has so maimed the descriptive history of the plates that it would be difficult for even the author to recognise the production of his own pen "

The slating is justified I have gone over the plates of Ricord and Acton to verify this statement, and can confirm it The real deception is in the text opposite the plates These are quite accurately translated from the French, but wherever such a remark as "M Ricord prescribed," or names of places such as "Paris" or "Belgium" occur, these are left out, in order, as the reviewer remarks,

> "that the reader might suppose that the drawing is made by the author, and the case happened in his practice; the swindle is made more complete by neither artist's nor author's name being mentioned "

The fraud is quite obvious, and yet, reading the book now, without prejudice, one is struck by its extraordinary lucidity, its broad sanity, its modern note, and its refusal to be intimidated by the authority of a great name Anyone conversant with the history of syphilis will remember that John Hunter considered secondary syphilis was non-contagious, that Ricord maintained the same, and that owing to the authority of these great names the truth did not become generally recognised until about 1870 It is true Babington at the Lock Hospital disputed it, and that Dr Wallace, of Dublin, published in THE LANCET (April 23rd, 1836, p 132) an account of how he inoculated five healthy persons with secondary syphilis and produced primary sores therefrom But no one seems to have believed him at the time Whether Bostwick was acquainted with Wallace's work is doubtful, but at any rate we find him vigorously maintaining in 1848, on pages 131 and 132 of his book, the present modern view

All through my copy of the book are pencilled notes, as I have mentioned before, and certainly the author is ill treated, in view (it must be remembered

Correspondence.

3 To find in what per cent of cases there is severe pain, slight pain, and no pain

4 To note details in exceptional and special cases and the causes of these phenomena and the length of dying time

5 To determine the characteristics and differences in dying between infants, children, adolescents, adults before middle life, during middle life, in old age, and from 80 to 100 years of age, including points under numbers 2, 3, and 4 for their ages

6 To present eventually a general picture of the dying time, based upon a sufficient number of observations, and with instruments of precision when possible

7 That with such knowledge the treatment of patients during the dying time may be more humane and delicately done

8 That in cases that are liable to be painful, proper precautions may be taken in advance, so that pain may be avoided or greatly lessened

9 That finally the knowledge of the dying time may be so increased that physical death will cease to be feared or dreaded by all persons, since through such knowledge pain may be practically eliminated and death may be made easy, gentle, and placid

I am myself seeking opportunity to make observation on cases of death, and I would consider it a great favour if any physician who makes observations and studies of cases during the dying time will send me a copy of his notes and results, for which due credit will be given when sufficient data are received to justify publication

I am, Sir, yours faithfully,
(Dr.) ARTHUR MACDONALD,

The Congressional Apartments, 100 E Capitol-street, Washington, D C

CHENOPODIUM FOR ANKYLOSTOMIASIS

To the Editor of THE LANCET

SIR,—Mr Paget's recent paper on the determination of the ascaridol content of oil of chenopodium, to which Messrs Burroughs Wellcome and Co call courteous attention in your issue of Sept 4th, shows that the constants laid down for that oil in the U S P are valueless unless the oil is a genuine one, since they can be reproduced by skilful adulteration, and, moreover, that the means advised in that Pharmacopœia for determining the ascaridol content are not effective in such an adulterated oil With a genuine oil, however, the old methods of estimating ascaridol, especially the specific gravity test, are shown to be fairly or actually accurate Accordingly if one may assume, as seems reasonable that the bulk of the oil used generally in anthelmintic work has been genuine the findings of Mr Paget's careful investigation authorise little misgiving in the continued use of the mass of information which has been accumulated in the tropics on the administration and effects of oil of chenopodium

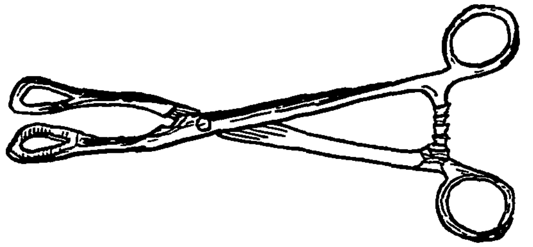
The letter under consideration raises a second point of equal practical importance Burroughs Wellcome and Co have produced an oil of chenopodium having an ascaridol content of 90 per cent and upwards In 1 2 c cm of this oil there is as much ascaridol as in about 1 8 c cm of an ordinary sample Put otherwise, to give 1 2 c cm of this preparation is equivalent to giving 1 8 c cm of an ordinary sample, while a dose of 1 5 c cm is equivalent to 2 25 c.cm In order to administer the ordinary dose of ascaridol, the dose of this particular oil must be only 0 8 c cm , a vital matter seeing how slight must sometimes be the margin between safety and anxiety in the case of ascaridol, equally with that of the other anthelmintics of which we have present knowledge

I am, Sir, yours faithfully,
Ealing, W , Sept 10th, 1926 CLAYTON LANE.

A PLEA FOR THE PERMANENT ABOLISHMENT OF THE "LINGUOTRITE"

To the Editor of THE LANCET.

SIR,—The "linguotrite" or tongue-crusher, is a brutal instrument which is still far too frequently found in the anæsthetist's tray of our hospitals up and down the country I am not implying that any professional anæsthetist would think of applying such an instrument to the tongue of his patient, but in the heat of the moment, when it suddenly becomes necessary to draw the tongue forward, as long as this contraption is at hand it will continue to be used by those whose duty it is to administer anæsthetics For weeks after its application the tongue is swollen and painful The bruising and subsequent inflammation constitutes a clinical entity—linguotritic glossitis I have observed several examples of this condition, which may be said to be the only omission from that masterpiece of surgical monographs, Butlin's "Diseases of the Tongue" The remedy is simple The linguotrite should be once and for all relegated to the dust-bin, and a pair of rational tongue forceps substituted



I am, Sir, yours faithfully,
Sept 10th, 1926 HAMILTON BAILEY

THE PATHOLOGICAL SERVICE OF THE GENERAL HOSPITAL

To the Editor of THE LANCET

SIR,—I entirely agree with Dr Powell White The pathologist has quite enough to put up with in competition with commercial, greater hospital, and university laboratories without having his own hospital interfering with his private work As to hospital paying a stipend and receiving rent (which would be practically impossible to assess) the hospital would be giving with one hand and receiving with the other, the pathologist remaining a paid servant, giving hospital cases precedence and possibly losing private work

I think the only satisfactory solution has been found here The hospital provides the laboratory and its equipment; the pathologist is a member of the honorary medical staff, and he practises as a specialist consultant in the strictest sense He also does a good deal of public health work, being paid according to an agreed scale of fees for each item He is his own master, he does not give preference to any case, hospital or private, he takes them as they come on their necessity. He certainly has to work very hard, and consulting specialist practice in the country is not brilliantly remunerative but he retains his self-respect and makes enough to live on with the ordinary decencies of life, although he cannot afford a car, which is not a professional necessity in his case.

I am, Sir, yours faithfully,
H ST ARNAUD AGATE

Pathological Department, General Infirmary,

JUSTICE FOR HOMER BOSTWICK

To the Editor of THE LANCET.

SIR,—There has recently come into my hands an example of literary piracy of an extremely interesting type which, for historical and other reasons, I should like to comment upon The pirate was a Dr. Homer Bostwick, who practised in New York between 1840 and 1870 The victims were Philippe Ricord, the famous French syphilologist, and his London pupil, William Acton.

Briefly the facts are as follows · In 1848 there appeared a volume, "A Complete Practical Work on the Nature and Treatment of Venereal Diseases, and other Affections of the Genito-Urinary Organs of the Male and Female" by Homer Bostwick, M D New York Burgess Stringer and Co . 1848 Bostwick sent a copy to THE LANCET for review inscribed "Thomas Wakley J Henry Bennett With the respects of the author" It is this copy which is now in my possession The inscription, I think, is in the author's handwriting because Bennet's name is wrongly spelt Why a single copy should have been sent between two men is not very obvious Possibly it was economy Henry Bennet was obstetric physician to the Royal Free Hospital at the time wrote for many years on THE LANCET staff, and was a friend of the Wakley family. The copy contains a series of caustic pencilled notes in the margins, on which the review, to be presently commented upon was afterwards built Apparently this is the only copy of the work in London; and I think, it must have been sent to Acton as a curiosity of piracy after Wakley had finished with it Acton's library passed to Sir Alfred Cooper, formerly senior surgeon to the London Lock Hospital, and from Cooper's library it, with other books of Acton, came to me Probably after the castigation which it received in THE LANCET the book fell dead on the market. And yet, in spite of everything said and truly said, against it, re-reading it now, nearly 80 years after, with an unbiased mind, I have been much impressed by certain opinions expressed and statements made, which, unorthodox in their day have since been proved correct Bostwick may have been a pirate, but he was also an acute clinician; and it is in the hope that some reader may be able to supply details about this forgotten author that I wish to resurrect the matter

The review appeared in THE LANCET of 1849, vol 1, p 401 It begins —

> "We doubt, brother Jonathan if it was a smart trick in you to send us this book for review So long as it occupied the shelves of your publisher, in Broadway or was read in the repudiating States, the deception might have been undiscovered . . but with us your fine plumage cannot conceal your daw's carcass, for your book contains nothing good but what you have pillaged from this side of the Atlantic. . "

Imagine starting a review thus in these days! But at that time there was considerable irritation in England against the United States, because certain individual States had borrowed money for railway and other public services, and when the interest became due had repudiated responsibility, leaving the bond-holders high and dry. But why visit the sins of defaulting States on an unfortunate medical writer? Again I quote from the review :—

> "In looking over the American annals of literature, we must all be painfully struck with the injustice of United States men in seizing our best surgical works and reprinting them as soon as published, with what are called Notes by Dr This or Observations by Mr. That . Doubtless it is easier to steal a book than write one, even though it contain trash but we very much question if this dishonest system is likely to protect or foster native talent, any more than it will improve national morals or promote international respect and brotherly feeling"

Here the reviewer is giving vent to his indignation as a writer upon seeing literary property stolen before his eyes, and even now the United States remain the only great nation refusing to recognise international copyright, even though large sums of American money reach English authors.

Having thus pilloried the States, and the publishers' morals, the reviewer returns to Bostwick thus .—

> "It was, however, left for Dr Bostwick to outvie any of his countrymen in injustice to authors on this side of the Atlantic In a large, handsome quarto, with coloured plates, woodcuts, and bold type, he has, under his own name, published a book on Venereal Diseases, which, almost from beginning to end, has been plundered from the works of M Ricord and Mr Acton."

The great feature of the work, the profusion of coloured plates is thus dealt with .—

> "'Some of the drawings'" Bostwick says, "'I have borrowed from the great work of Ricord, others from Acton and some I have taken directly from life.'"

On this it is commented —

> "Whatever his 'returns' may be, his 'borrowings' have been pretty considerable We have looked into the works in question, and believe we can trace every coloured plate or woodcut (about 70 in number), except one to English or French treatises But our transatlantic daw, not content with this wholesale borrowing, as he calls it, has so maimed the descriptive history of the plates that it would be difficult for even the author . to recognise the production of his own pen."

The slating is justified I have gone over the plates of Ricord and Acton to verify this statement, and can confirm it The real deception is in the text opposite the plates These are quite accurately translated from the French, but wherever such a remark as "M Ricord prescribed," or names of places such as 'Paris" or 'Belgium" occur, these are left out, in order. as the reviewer remarks.

> "that the reader might suppose that the drawing is made by the author, and the case happened in his practice; the swindle is made more complete by neither artist's nor author's name being mentioned"

The fraud is quite obvious and yet, reading the book now. without prejudice, one is struck by its extraordinary lucidity, its broad sanity. its modern note. and its refusal to be intimidated by the authority of a great name. Anyone conversant with the history of syphilis will remember that John Hunter considered secondary syphilis was non-contagious, that Ricord maintained the same, and that owing to the authority of these great names the truth did not become generally recognised until about 1870 It is true Babington at the Lock Hospital disputed it, and that Dr. Wallace, of Dublin, published in THE LANCET (April 23rd, 1836, p 132) an account of how he inoculated five healthy persons with secondary syphilis and produced primary sores therefrom But no one seems to have believed him at the time Whether Bostwick was acquainted with Wallace's work is doubtful. but at any rate we find him vigorously maintaining in 1848 on pages 131 and 132 of his book, the present modern view.

All through my copy of the book are pencilled notes, as I have mentioned before, and certainly the author is ill treated, in view (it must be remembered

of what we now know Against a passage describing how some patients acquired syphilis by rubbing the legs of sufferers from periosteal nodes the note is—‘ Out-Herod's Herod ” Against a statement that syphilis of the lung may occur and simulate consumption is the comment “opposed to facts” Bostwick's explanation of Colles's Law (p 181) that the reason a syphilitic child cannot infect its mother is because she already has the disease herself is the earliest correct one known to me There is a curious story (p 211) of how the author produced gonorrhœa in two male patients by passing a bougie on them six weeks after he had used it on a case of acute gonorrhœa The bougie had been washed carefully and put aside, he says, but on examining it he found a small crack in which he surmised the “ virus ” had remained The remark of the reviewer on the margin is “ bosh ”

No one can complain of a reviewer whose opinions are the standard opinions of his time, but when the work dealt with is in front of that time the situation is a hard one At any rate, true views ought to be credited to their author when they have been confirmed later, and Bostwick seems to have been something of a pioneer

What position he held amongst his contemporaries it is difficult to discover He is responsible for three books (1) One on “ Seminal Diseases,” the second edition of which was reviewed slightingly in The Lancet, 1849, vol i, p 97. (2) The work on syphilis, &c, on which we have been commenting, 1848 (3) A curious brochure entitled, “ An enquiry in the cause of natural death, or death from old age Developing a new and certain method of preventing the consolidation or ossification of the body, and of thus indefinitely prolonging vigorous, elastic, and buoyant health, and of rendering parturition easy and safe ” 8vo, pp 152 N Y Stringer and Townsend, 1851. Nothing then appears to have come from his pen until 1871, when he started a journal ‘ Bostwick's Medical and Surgical Journal,” Nos 1 and 2, January, February, 1871 Only two issues were published Probably he died somewhere about this time Perhaps some American reader can supply further details

I am, Sir, yours faithfully,
J. Johnston Abraham

Harley street, W, Sept 13th, 1926

REGISTERED NURSES' BUREAU

To the Editor of The Lancet

Sir —May I be allowed to draw the attention of my professional colleagues to the fact that the R N B (which is not being run for profit) is in a position to send to them any kind of nurse desired from its staff which is now thoroughly organised, and to express the hope that they will endorse and support this effort to *protect* the nurse (in eliminating for her the heavy weekly commission she has hitherto had to pay upon her fees) by applying to it when requiring nurses

I am glad to be able to assure my colleagues that the R N B is thoroughly organised on excellent business as well as strictly professional lines, and embraces every nursing activity and requirement in surgery and medicine It has the endorsement of leading members of both professions, including members of the General Nursing Council and of the Council of the College of Nursing Its professional side is entirely in the hands of specially chosen trained State-registered nurses, to whom alone a practitioner telephoning gives his instructions The address is 55, Chancery-lane, and the telephone is Holborn 0846

I am, Sir, yours faithfully,
W Arbuthnot Lane,
Chairman, Honorary Advisory Committee

Cavendish square, W, Sept 13th, 1926

Obituary.

HERBERT WILLIAM PAGE, M Ch Camb, F R C S Eng,

CONSULTING SURGEON, ST. MARY'S HOSPITAL, LONDON

We regret to announce the death of Mr Herbert William Page, consulting surgeon to St Mary's Hospital, which occurred at Sedgecombe House, Farnham, his home in the country, on Sept 9th, in his 81st year He had for a considerable period retired from active practice as a consulting surgeon, when he was famous as an expert in the difficult pathological field of railway injury

Herbert William Page was born in 1845, the son of a well-known practitioner in Carlisle, William Bousfield Page, and was educated in Edinburgh and later at Christ's College, Cambridge At Cambridge he graduated in Arts, his medical education being at the London Hospital The staff at “ the London ” at that time included three particularly great men—Hughlings Jackson and Gawen Sutton were the lecturers on pathology and morbid anatomy, while Jonathan Hutchinson was a senior on the surgical side The influence which these learned men and inspiring teachers had upon Page is illustrated by the fact that although he decided early to follow the career of a consulting surgeon, in all his institutional and public and private work he displayed general familiarity with the problems of medicine In 1870 he graduated M B at Cambridge, and almost immediately obtained a commission in the German Army on the outbreak of the Franco-Prussian War. He served as a surgeon through the war, and on his return to England he joined his father for a short time in practice at Carlisle, but it was not long before he made up his mind to return to London and the practice of surgery He took the F R C S Eng and made his start as surgical registrar to his old hospital He was elected assistant surgeon at St Mary's Hospital in 1876 and served on the staff of the hospital for the full term of 30 years as surgeon and teacher when he was elected consulting surgeon

Mr. H. W Page

Page's surgery was marked by an earnest conscientiousness and by an almost meticulous attention to detail He was the first surgeon at St Mary's to rely on instruments and dressings sterilised by heat rather than by antiseptics, and while he was essentially conservative, he was not reactionary, indeed, in 1887 he performed for the first time at his hospital the operation of gastro-enterostomy The patient was a man of 48 who had suffered from malignant obstruction of the pylorus for several months, the operation gave him much relief and he lived in comparative comfort for 72 days In a paper read to the Royal Medical and Chirurgical Society 18 months later Page reviewed the results of 38 cases in which the operation had been done, and pleaded for its more common use in this country. It was, he said, an operation distinctly justifiable and to be recommended, for it was capable of bringing relief to the distressing symptoms incidental to pyloric obstruction and was thereby in all probability the means of prolonging life Forty years ago such arguments were really advanced

'To the average student," writes one of Page's intimate colleagues, "Page was not an attractive teacher His formal lectures were scholarly and profound and were expressed in the most polished English, but they lacked those dramatic qualities which endow dull facts with life. He was seen at his best in an informal clinical lecture, usually prepared for the purpose of demonstrating certain cases in the wards Models of clear thinking and of lucid exposition many of these lectures remained in the memories of those who heard them, to be applied years afterwards to the elucidation of similar problems In 1897 he collected 12 of these lectures and published them under the title of 'Clinical Papers on Surgical Subjects' a little book which can still be read with advantage by even the youngest He possessed to a degree, vouchsafed to few, the power of speech A wonderful choice of words a clear diction and a melodious voice gave to his speeches a distinction which was still further enhanced by his clarity of thought and by a touch of whimsical humour. A speech from Page decorated any occasion, however prosaic, and translated it at once from the common-place. The possession of these qualities combined with his intimate knowledge of the subject, rendered him an invaluable witness at a time when the railway companies considered it necessary to contest excessive claims against them for damages as the result of accidents The legal opinion of Page as an expert witness cannot better be illustrated than by quoting the shorthand writer's notes of Lord Chief Justice Coleridge's summing up in the case of Milsom v the L & N W Rly Co, 1879

> "This I will say that whereas it is most difficult very often to follow the reasons and to apply the ordinary rules of common sense to the evidence given by Dr R and Mr G I do not think any man of the most ordinary common sense would have the least difficulty in following the evidence of Mr Page and in ascertaining exactly and definitely what Mr Page meant to say. Whether you believe Mr Page is another matter, but he is such a comprehensible and intelligible witness as I very seldom have heard in the witness box. A child might understand him, and he gave his evidence with lucidity and firmness Of course it is in your hands, of course it is for you to say whether you believe him or not, but as far as one could judge, a more cool and intelligent man a person who seemed to estimate the value of the words he is using it has seldom been my good fortune to see before a judge and jury"

"Page's character was distinguished by the simplicity of true greatness He was singularly direct, incapable of any finesse and often embarrassingly frank His reserve almost amounted to shyness and he shrank from anything approaching publicity or advertisement He had a great capacity for friendship and his loyalty to his old friends many of whom dated from his student days was a source to him of some distress as he outlived so many To those who remain and who have enjoyed the charming intimacy of his friendship his loss is irreparable"

To return to Page's interest in railway injuries—shortly after his connexion with St Mary's Hospital he was appointed surgeon to two great railways—the London and North-Western and the Great Western—and this occurred at a time when the after-results of railway accidents were exercising very much the public mind, and when medical opinions on the subject were widely sought in the law courts. It is true that the time had gone by when universal medical support could be found for the beliefs prevalent 20 years before, that the physical conditions of the public were suffering ominously as the result of the development of railway travelling. As far back as 1862 there had appeared in THE LANCET the results of a detailed inquiry into the influence of railway travelling on public health, in which the Great Northern Railway and the Great Western Railway, among others, were two of the lines inspected from this standpoint; the conclusions of this inquiry did much to remove apprehensions with regard to huge and mysterious physiological damage dependent upon alterations of atmospheric pressure, upon the great pace of transit and so on, but the sequelæ of actual accidents occurring to certain patients remained unexplained Some four years later Erichsen wrote a work on Concussion of the Spine, the condition identified by him as of occurrence in railway accidents in particular and his views were accepted by the medical profession though with some reserve, certain cases for compensation suggesting that Erichsen's views had conferred the appearance of physical reality upon imaginary things The medical profession was divided in view despite the apparent acquiescence in the attitude of a great leader, and Page came to play a leading part in the matter. In 1881 the subject for the Boylston prize of the University of Harvard was 'Injuries of the back without apparent mechanical lesions, in their surgical and medico-legal aspects" This prize Page won for an essay founded upon his personal experience as surgeon to two great railways, and the essay, enlarged and somewhat altered in title, became the first edition of his well-known work on the subject of railway injuries The book was an immediate success In it there were tabulated a series of cases of railway injury which, on the one hand presented much the clinical picture which had already been drawn by Erichsen, and in which, on the other hand no evidence satisfactory to Page could be found of any injury whatever to the spinal cord or its membranes. He was able to account for many of the symptoms, which had been regarded as of a particularly malign character, inasmuch as they illustrated degeneration of the spinal cord, as the expression of traumatism to bones or muscles and having no such sinister expectations he consequently came into conflict with Erichsen's followers who had evolved for the condition, named Concussion of the Spine, a complete pathology. Page's conflict with Erichsen's views was openly expressed, and as those views were the ones generally adopted by medical witnesses in cases for damage, the expression of his convictions required courage Page spoke openly; he was even reproved for his uncompromising attitude towards his seniors and he prevailed, how completely will be seen by anyone who consults the surgical manuals of the eighties and compares them with those a few years later From this time forward Page was recognised as an authority on railway injuries, and the part played by traumatic neurasthenia in the symptoms following accidents by rail was generally accepted His position regarding "railway spine" was That it was a mental condition caused partly by the pain due to a definite injury to ligamentous and muscular structures of the spinal column, and partly by the apprehension of the unknown consequences which might flow from this He held that the condition was maintained and augmented by auto-suggestion and by the fear that all this suffering would not be sufficiently compensated He was careful not to use the word malingering His conception displaced the view that the symptoms of which the sufferers complained were due to a "Concussion of the spinal

cord ” analogous to the condition known as “ Concussion of the brain ” This work gained Page the unusual distinction for a surgeon of the Presidency of the Neurological Society

At the Royal College of Surgeons of England he was elected a member of the Council in 1899 and served on that body for eight years, and for the same period he was a member of the Court of Examiners He was also an examiner in surgery at the Universities of Cambridge, Oxford, and Birmingham, and in the discharge of these duties he displayed the qualities of accuracy and sound judgment that marked his surgical work He retired from practice 20 years ago, which is a long period when a professional career is under consideration, but he will be remembered for those qualities by those who came into contact with him as colleague or teacher

He married first a daughter of the Rev Christopher Parker, by whom he had two daughters, and secondly Kathleen, daughter of the Rev Canon Houghton, who survives him.

THE LATE DR E I BOSTOCK —Dr Edward Ingram Bostock, who died at Horsham on Sept 4th in his eighty-third year, was a son of the late Dr J S Bostock He studied medicine at St Bartholomew's Hospital, and soon after qualifying, in 1864, joined his father in practice at Horsham As a practitioner Dr Bostock was keen and sympathetic, and his diagnostic ability won the implicit confidence of his patients When visiting he used to drive round in a high carriage with large yellow-painted wheels, and his practice covered a large area in North Sussex. Nevertheless, he found time to take an active interest in parochial matters for over 40 years He was one of the original members of the West Sussex County Council, and a Justice of the Peace, in his early days he was identified with the Volunteer movement All his six sons served in the Army during the war, and three were killed in action Dr Bostock's health gradually declined after the death of his wife in 1921, but he remained a well-known figure in Horsham, and there was a large gathering at his funeral to show the respect in which he was held

THE LATE DR J H TONKING —After attending to his practice as usual on the day before, Dr John Herbert Tonking was found on Sept 4th to have died in his sleep He was 62 years of age, and was the son of the late Mr C H Tonking, for many years chemist at Camborne Educated at Ford's School, Camborne, he served as apprentice to a local doctor before going to London for his medical studies After taking the conjoint qualification in 1886 he became house surgeon at St Thomas's Hospital, and two years later graduated as M B in the University of London Thirty-nine years ago he went back to his native town, where his services came to be greatly valued He was consulting surgeon to St Michael's Hospital, Hayle, and to Helston Cottage Hospital, and held a number of other local appointments Besides articles in medical journals he submitted a Note on the Tubercular Nature of the Final Stage of Miners' Phthisis to the Royal Commission set up to inquire into the mortality of Cornish miners Dr Tonking had three children His elder son was killed in France during the war, and his daughter died recently He leaves a widow

---

EGYPTIAN SCHOOL OF MEDICINE —The Egyptian Government has decided not to go on with its plan to build a new school of medicine with a hospital at Abbassia, and announces its intention to revert to the original scheme for building on the Manial Roda Island site, as recommended by an expert commission in 1919

THE FUTURE OF VOLUNTARY HOSPITALS —In a speech at the mayoral lunch when Princess Mary laid the foundation-stone of the new infirmary buildings at Harrogate, Sir Berkeley Moynihan expressed the opinion that in all hospitals there must be established paying beds and paying wards He believed that in the future, even the richest people “ would look upon it as their duty, certainly their need, to have hospital treatment ” In America and Canada hospital treatment was “ far better than anything even the richest of private patients could get in ordinary circumstances to-day ” He added that the old tradition of hospital construction would have to be broken, and that there is now “ a great opportunity for somebody to devise a new kind of hospital which will be cheap, easily capable of extension upon the original plan, and from the professional point of view of even greater efficiency than the old hospitals ”

Medical News.

MEDICAL WOMEN'S INTERNATIONAL ASSOCIATION —This association held a council meeting in Prague on August 26th and 29th. Lady Barrett, the President, took the chair, and reports of the activities of the various national associations were presented by the respective national corresponding secretaries The most recently formed association is that of Hungary, and Hungarian delegates attended the meeting for the first time In addition to the other business of the council, medical meetings were held, at which papers were communicated on (1) Tuberculosis and Pregnancy and (2) Women as Police Surgeons Representatives from the Czecho-Slovak Ministry of Health attended these, and took a prominent part in the discussions, a full report of which will be published in the next number of the *Medical Women's International Journal* The President gave a dinner to the delegates on the night preceding the council, at which she welcomed the Lord Mayor of Prague and other officials The association was also fortunate in having been invited to hold all its meetings in the old Town Hall. The Lord Mayor and town councillors received the delegates and entertained them at luncheon and the State railways and Ministry of Health arranged a full programme, granting facilities to the delegates to visit various spas, hospitals, and institutions

WEEKLY CONTRIBUTIONS AT OXFORD —The governors of the Radcliffe Infirmary at Oxford report that the weekly contribution scheme has been a brilliant success During the last financial year it brought in £25,400, or 60 per cent of the total income

POST-GRADUATE COURSES IN VIENNA —In our issue of Sept 4th (p 519) a note was published on courses given by the Medical Faculty at Vienna The address at which application may be made to the Secretary of the Post-graduate Medical Courses should have been given as Schlösselgasse 22, Vienna VIII, and not Schlösselgasse 32

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.—The winter session will be formally opened on Friday, Oct 1st, at 2 30 P M., when the introductory address will be given by Sir Humphry Rolleston, Regius Professor of Physic in the University of Cambridge The annual dinner of past and present students will be held on the same day at 7 for 7 30 P M at the Criterion Restaurant, Piccadilly Dr Frank H Jacob will take the chair

LONDON HOSPITAL: CHILDREN'S DEPARTMENT —The quarterly report of the house committee states that the reorganised children's out-patient department, which is being financed by the East-End Tradesmen's Association, started work on July 15th It is intended that the department shall act as a consultative centre and for the treatment of more difficult cases The demands upon it have increased so rapidly that the days of opening have already had to be increased from two to three a week

NORTHERN INFIRMARY, INVERNESS —Towards the £100,000 required for the reconstruction and enlargement £40,000 has been received or promised and the directors intend to begin the work so soon as £50,000 is available They state that the enormous increase in the number of motorists, with the consequent danger of accidents, has made enlargement imperative “ at the earliest possible moment ” A number of owners and tenants of grouse moors have sent the proceeds of their sales of game to the infirmary

DISCOVERY OF HOSPITAL RECORDS —Upon clearing out the roof of the Royal Hampshire County Hospital at Winchester two portraits in oil, a commemorative armorial tablet and the first minute-book of the court of governors were discovered One of the portraits represents the Rev Dr Alured Clarke, the founder of the hospital, dated 1736 The other was that of Alderman Edward Taunton, of Southampton, whose connexion with the institution is being investigated The minute-book is also dated 1736 The armorial tablet records that, in 1760, Colonel Narbonne Berkeley fitted up the board room at his own expense

DONATIONS AND BEQUESTS —The late Sir John Williams, Bart, who left estate of the gross value of £123,742, with net personalty £121,012, bequeathed £2000 to University College Hospital, London, and £1550 and any of his books, pictures, MSS, &c, they may select to the National Library of Wales The residue of the property which, after other bequests to servants, will amount to nearly £100,000 is to be divided between the National

Library of Wales and the University College of Wales, Aberystwyth —The late Sir Frederick W Mott left estate of the gross value of £22,211, with net personality £16,862 After a small personal bequest he left the residue of the property, subject to certain trusts, failing which, with remainder to the University of London for the endowment or partial endowment of a Professorship of Psychological Medicine "at my Alma Mater," the Medical School of University College Hospital, stating that he did not wish the professorship to be founded until there should be sufficient accommodation for the study and treatment of early cases of mental disorder either in wards in University College Hospital or in an affiliated mental hospital —Mr R B Sharp and Mr F B Sharp, of the firm of John Sharp and Sons, jute spinners, Dundee, have made a gift of £30,000 to the Dundee Royal Infirmary for the purpose of building and equipping a new maternity hospital —Mr Charles W Bell-Raisbeck, M A., assistant master of Cheltenham College, besides many other institutional and other bequests, left £1000 to the Cheltenham General Hospital —From the residue of the property of Mr Harry Watson, of Bath, the Cottage Hospital, Whitby, Yorks, will receive about £850 the Royal United Hospital, Bath, the British Hospital, Buenos Aires, St Dunstan's Home for the Blind, the Royal Hospital for Incurables, Putney, and Dr Barnardo's Homes, each, will receive about £560 —Miss Alice Wild of Oldham, left £1000 to Oldham Royal Infirmary and £500 to Henshaw's Blue Coat School —Mr Frederick Thomas Alton, of Stamford, Lincolnshire, a pawnbroker, left estate of the gross value of £57,852 The testator, after bequests amounting to about £16,000, left the residue of his property to accumulate during the longest period allowed by law, but not later than the year 2000, and then the capital and accumulated interest to be divided equally between the Manchester Infirmary, the Gloucester Infirmary, Guy's Hospital, and St Thomas's Hospital, London, and the British and Foreign Bible Society

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT 4TH, 1926

Notifications —The following cases of infectious disease were notified during the week —Small-pox, 79 (last week 90), scarlet fever, 1260, diphtheria, 716, enteric fever, 71, pneumonia, 395, plague, 2, puerperal fever, 44, cerebrospinal fever, 4, acute poliomyelitis, 41, acute polioencephalitis, 2, encephalitis lethargica, 29, dysentery, 8, ophthalmia neonatorum, 107 There were no cases of cholera or typhus fever notified during the week. The 2 cases of plague, as mentioned in our news columns last week, were notified from Liverpool

Deaths —In the aggregate of great towns, including London, there were no deaths from small-pox, 3 (2) from enteric fever, 6 (0) from measles, 6 (4) from scarlet fever, 27 (4) from whooping-cough, 30 (5) from diphtheria, 161 (33) from diarrhœa and enteritis under two years, and 19 (3) from influenza The returns from diarrhœa and enteritis again show a moderate rise, but have by no means reached the figures of the corresponding week a year ago The figures in parentheses are those for London itself

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Castleton, Derbyshire

Births, Marriages, and Deaths.

BIRTHS

CLARK —On Sept 7th, at Walker street, Edinburgh, the wife of Alfred J Clark, M.D, of a son.

FOULKES —On Sept 3rd, to Mary G Foulkes, M R C S, L R.C P, the wife of R K Foulkes, M.B, B S, of 6, Barnfield crescent, Exeter—a daughter

HOOPER —On Sept 6th, at the City Mental Hospital, Fulford, York, the wife of Reginald Hooper, M B, of a daughter

KILNER —On Sept 8th, at Abbotsford, Mostyn avenue, Llandudno the wife of S D Kilner M D, of a daughter

ROSS —On Sept 8th, at the Avenue Nursing Home Cheam, the wife of J N MacBean Ross, *M C*, M D, F R C S, of Worcester House, Sutton, Surrey, of a son

MARRIAGES

FAIRBAIRN—MORE GORDON —On Sept 11th, at Old St Paul's Church Edinburgh, William Ronald Dodds Fairbairn M.A, M.B Ch B, Dipl Psych. Edin, to Mary Ann, only daughter of the late Mr Harry More Gordon, of Charleton and Kinnaber, Forfarshire, and Mrs More Gordon, Albert-terraace, Edinburgh

MESSER—DELVES —On Sept 9th, at the Parish Church, Long Preston Yorkshire, William Messer M.B, to Catherine Monica Mary daughter of the late Thomas Hirst Delves, and of Mrs Delves, Lochinvar, Long Preston

DEATHS

BURKITT —On Sept 7th at a nursing home in London after an operation William Arthur Handcock Burkitt M D of Goulburn New South Wales, Australia aged 63

N.B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages and Deaths cord " analogous to the condition known as " Concussion of the brain " This work gained Page the unusual distinction for a surgeon of the Presidency of the Neurological Society

At the Royal College of Surgeons of England he was elected a member of the Council in 1899 and served on that body for eight years, and for the same period he was a member of the Court of Examiners He was also an examiner in surgery at the Universities of Cambridge. Oxford, and Birmingham, and in the discharge of these duties he displayed the qualities of accuracy and sound judgment that marked his surgical work He retired from practice 20 years ago, which is a long period when a professional career is under consideration, but he will be remembered for those qualities by those who came into contact with him as colleague or teacher

He married first a daughter of the Rev Christopher Parker, by whom he had two daughters, and secondly Kathleen, daughter of the Rev Canon Houghton, who survives him

THE LATE DR E I BOSTOCK —Dr Edward Ingram Bostock, who died at Horsham on Sept 4th in his eighty-third year, was a son of the late Dr J S Bostock He studied medicine at St Bartholomew's Hospital, and soon after qualifying, in 1864, joined his father in practice at Horsham As a practitioner Dr Bostock was keen and sympathetic, and his diagnostic ability won the implicit confidence of his patients When visiting he used to drive round in a high carriage with large yellow-painted wheels, and his practice covered a large area in North Sussex. Nevertheless, he found time to take an active interest in parochial matters for over 40 years He was one of the original members of the West Sussex County Council, and a Justice of the Peace, in his early days he was identified with the Volunteer movement All his six sons served in the Army during the war, and three were killed in action Dr Bostock's health gradually declined after the death of his wife in 1921, but he remained a well-known figure in Horsham, and there was a large gathering at his funeral to show the respect in which he was held

THE LATE DR J H TONKING —After attending to his practice as usual on the day before, Dr John Herbert Tonking was found on Sept 4th to have died in his sleep He was 62 years of age, and was the son of the late Mr C H Tonking, for many years chemist at Camborne Educated at Ford's School, Camborne, he served as apprentice to a local doctor before going to London for his medical studies After taking the conjoint qualification in 1886 he became house surgeon at St Thomas's Hospital, and two years later graduated as M B in the University of London Thirty-nine years ago he went back to his native town, where his services came to be greatly valued He was consulting surgeon to St Michael's Hospital, Hayle, and to Helston Cottage Hospital, and held a number of other local appointments Besides articles in medical journals he submitted a Note on the Tubercular Nature of the Final Stage of Miners' Phthisis to the Royal Commission set up to inquire into the mortality of Cornish miners Dr Tonking had three children His elder son was killed in France during the war, and his daughter died recently He leaves a widow

---

EGYPTIAN SCHOOL OF MEDICINE —The Egyptian Government has decided not to go on with its plan to build a new school of medicine with a hospital at Abbassia, and announces its intention to revert to the original scheme for building on the Manial Roda Island site, as recommended by an expert commission in 1919

THE FUTURE OF VOLUNTARY HOSPITALS —In a speech at the mayoral lunch, when Princess Mary laid the foundation-stone of the new infirmary buildings at Harrogate, Sir Berkeley Moynihan expressed the opinion that in all hospitals there must be established paying beds and paying wards He believed that in the future, even the richest people " would look upon it as their duty, certainly their need, to have hospital treatment " In America and Canada hospital treatment was " far better than anything even the richest of private patients could get in ordinary circumstances to-day " He added that the old tradition of hospital construction would have to be broken, and that there is now " a great opportunity for somebody to devise a new kind of hospital which will be cheap, easily capable of extension upon the original plan, and from the professional point of view of even greater efficiency than the old hospitals "

Medical News.

MEDICAL WOMEN'S INTERNATIONAL ASSOCIATION —This association held a council meeting in Prague on August 26th and 29th Lady Barrett, the President, took the chair, and reports of the activities of the various national associations were presented by the respective national corresponding secretaries The most recently formed association is that of Hungary, and Hungarian delegates attended the meeting for the first time In addition to the other business of the council, medical meetings were held at which papers were communicated on (1) Tuberculosis and Pregnancy and (2) Women as Police Surgeons Representatives from the Czecho-Slovak Ministry of Health attended these, and took a prominent part in the discussions a full report of which will be published in the next number of the *Medical Women's International Journal* The President gave a dinner to the delegates on the night preceding the council, at which she welcomed the Lord Mayor of Prague and other officials The association was also fortunate in having been invited to hold all its meetings in the old Town Hall The Lord Mayor and town councillors received the delegates and entertained them at luncheon and the State railways and Ministry of Health arranged a full programme, granting facilities to the delegates to visit various spas, hospitals, and institutions

WEEKLY CONTRIBUTIONS AT OXFORD — The governors of the Radcliffe Infirmary at Oxford report that the weekly contribution scheme has been a brilliant success During the last financial year it brought in £25,400, or 60 per cent of the total income

POST-GRADUATE COURSES IN VIENNA —In our issue of Sept 4th (p 519) a note was published on courses given by the Medical Faculty at Vienna The address at which application may be made to the Secretary of the Post-graduate Medical Courses should have been given as Schlösselgasse 22, Vienna VIII, and not Schlösselgasse 32

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.—The winter session will be formally opened on Friday, Oct 1st, at 2 30 P M, when the introductory address will be given by Sir Humphry Rolleston, Regius Professor of Physic in the University of Cambridge The annual dinner of past and present students will be held on the same day at 7 for 7 30 P M at the Criterion Restaurant, Piccadilly Dr Frank H Jacob will take the chair

LONDON HOSPITAL CHILDREN'S DEPARTMENT —The quarterly report of the house committee states that the reorganised children's out-patient department, which is being financed by the East-End Tradesmen's Association, started work on July 15th It is intended that the department shall act as a consultative centre and for the treatment of more difficult cases The demands upon it have increased so rapidly that the days of opening have already had to be increased from two to three a week

NORTHERN INFIRMARY, INVERNESS —Towards the £100,000 required for the reconstruction and enlargement £40,000 has been received or promised and the directors intend to begin the work so soon as £50,000 is available They state that the enormous increase in the number of motorists, with the consequent danger of accidents, has made enlargement imperative " at the earliest possible moment " A number of owners and tenants of grouse moors have sent the proceeds of their sales of game to the infirmary

DISCOVERY OF HOSPITAL RECORDS —Upon clearing out the roof of the Royal Hampshire County Hospital at Winchester two portraits in oil a commemorative armorial tablet and the first minute-book of the court of governors were discovered One of the portraits represents the Rev Dr Alured Clarke, the founder of the hospital, dated 1736 The other was that of Alderman Edward Taunton, of Southampton, whose connexion with the institution is being investigated The minute-book is also dated 1730 The armorial tablet records that, in 1760, Colonel Narbonne Berkeley fitted up the board room at his own expense

DONATIONS AND BEQUESTS —The late Sir John Williams, Bart, who left estate of the gross value of £123,742, with net personality £121,012, bequeathed £2000 to University College Hospital, London, and £1550 and any of his books, pictures MSS, &c, they may select to the National Library of Wales The residue of the property which, after other bequests to servants, will amount to nearly £100,000 is to be divided between the National

Library of Wales and the University College of Wales, Aberystwyth.—The late Sir Frederick W Mott left estate of the gross value of £22 241 with net personalty £16,862 After a small personal bequest he left the residue of the property, subject to certain trusts, failing which with remainder to the University of London for the endowment or partial endowment of a Professorship of Psychological Medicine "at my Alma Mater," the Medical School of University College Hospital stating that he did not wish the professorship to be founded until there should be sufficient accommodation for the study and treatment of early cases of mental disorder either in wards in University College Hospital or in an affiliated mental hospital —Mr R. B Sharp and Mr F B Sharp of the firm of John Sharp and Sons, jute spinners Dundee, have made a gift of £30 000 to the Dundee Royal Infirmary for the purpose of building and equipping a new maternity hospital —Mr Charles W Bell Raisbeck M.A., assistant master of Cheltenham College, besides many other institutional and other bequests left £1000 to the Cheltenham General Hospital —From the residue of the property of Mr Harry Watson of Bath, the Cottage Hospital, Whitby Yorks will receive about £850 the Royal United Hospital Bath, the British Hospital, Buenos Aires, St Dunstan's Home for the Blind, the Royal Hospital for Incurables, Putney and Dr Barnardo's Homes, each will receive about £560 —Miss Alice Wild of Oldham left £1000 to Oldham Royal Infirmary and £500 to Henshaw's Blue Coat School —Mr Frederick Thomas Alton, of Stamford Lincolnshire, a pawnbroker, left estate of the gross value of £57,852 The testator, after bequests amounting to about £16,000, left the residue of his property to accumulate during the longest period allowed by law, but not later than the year 2000, and then the capital and accumulated interest to be divided equally between the Manchester Infirmary, the Gloucester Infirmary Guy's Hospital, and St. Thomas's Hospital, London, and the British and Foreign Bible Society

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT 4TH, 1926

Notifications —The following cases of infectious disease were notified during the week —Small-pox, 79 (last week 90), scarlet fever, 1260 , diphtheria 716 enteric fever, 71 , pneumonia, 395 , plague, 2 , puerperal fever, 44 ; cerebrospinal fever, 4 , acute poliomyelitis, 41 , acute polio-encephalitis, 2 , encephalitis lethargica, 29 , dysentery, 8 , ophthalmia neonatorum, 107 There were no cases of cholera or typhus fever notified during the week. The 2 cases of plague, as mentioned in our news columns last week, were notified from Liverpool

Deaths —In the aggregate of great towns, including London, there were no deaths from small-pox, 3 (2) from enteric fever, 6 (0) from measles, 6 (4) from scarlet fever, 27 (4) from whooping-cough, 30 (5) from diphtheria. 161 (33) from diarrhœa and enteritis under two years, and 19 (3) from influenza. WHAT IS A MENTAL ILLNESS ? *

By Noel H M Burke, M R C S Eng , D P M Lond

Quite recently a curious diagnosis was found among the records of a patient This person was said to be suffering from "brain disease" and, in brackets, "functional" The label was the more amazing because there was no justification for any diagnosis of brain disease from the physical signs or symptoms, though there was reason to think there was a so-called functional disorder It is safe to assume that this evidence of confused thought was the work of one not well versed in the subject of medical psychology Yet in the last few months it has become apparent that those who are can be as careless in their approach to their own subject

At a recent meeting to discuss the early treatment of mental disease, someone spoke of his experience with malaria as a therapeutic agent for general paralysis of the insane In another meeting, at Bath last summer, the subject was supposed to be the prevention of mental disease, and much time was taken up with the consideration of nasal oral, and other sepsis, while a question was asked about a pure water-supply in some district

It is hard to understand the importance of sepsis in the causation of any mental disease at any rate in the sense implied by its advocates Nor is it easy to believe that an attack of malaria has any curative value in any mental disease, though we may be impressed by what is reported of its use in the treatment of general paralysis In other words, it is an error in the use of labels to class G P I as a mental disease, and there is loose thinking somewhere in the argument that gives to toxic absorption an important place in the ætiology of any truly mental illness

The Psychological Point of View

At first approach to this subject it seems quite easy to define a mental illness and to differentiate this group from that of the bodily illnesses, but the more one looks into the matter the less simple does it appear, and the more important are the difficulties to easy classification In the first place it is clear that the term mental illness must mean an illness of mind That, at least, seems to be the logical meaning of the words used We are at once called upon for a definition of mind, and at once we find disagreement amongst the experts, and a whole list of theories, each well supported by argument, from which we may choose that which seems most reasonable What is mind and what is its relation to body ?

Between monism, dualism, parallelism, epiphenomenalism, and so on, which is the view that approaches most nearly to the truth ? This is not, perhaps, the place for a laboured discussion of these questions, but we should be on safe ground and should meet with a good deal of agreement in selecting an Aristotelian form of definition for mind as being the sum total of the functioning of the whole organism This appears to be the most satisfactory way of viewing the matter Mind seems to be, not the manifestations of the activity of a limb, a brain, an eye or a tooth, but of a whole organism. It seems to depend on the existence of such organism or subject, and on the state of that subject in virtue of being alive

The elements of mentality are summed up in a way that all can accept under the headings of thinking, feeling, and striving Now if this be a satisfactory description of mind it would seem that a mental illness is an illness, not of a limb, a brain, or a tooth, nor of any material part of a subject, but of that general functional quality of the subject which is his mind Stoddart calls it mentation, and describes it as a process, to distinguish it from the mind which many regard as a thing Psychologically, a mental illness is one which is seated in those functionings which are subsumed under "thinking, feeling, and striving" as the main forms of mentality or mentation It is a disorder of memory, perception, emotion, wishing and doing, it prevents the making of normal adjustments to social and other environmental situations, including the internal environment of the subject himself

If this be an approximately true description of the essence of a mental illness, it is clear that the disorder is quite different from a brain disease or other purely bodily lesion, and that the mechanism of the two is different It follows that the causation is also different and in causation we have the great distinguishing feature A bodily illness is a disorder of some tissue, organ, or system, caused by intrinsic defect, noxious external influences, or a disturbance of the adequate balance between intrinsic strength and external stimuli Similarly, a mental illness is a disorder of mind caused by inherent defect, noxious external influences, or a disturbance of the adequate balance between attacking and defending forces In the case of the former, however, the external noxious influence is of material nature , in the case of mental illness it is of a mental nature Thought does not add a cubit to the stature Food, light, and exercise may do so A blow hurts a boy's body what he thinks about it may throw his mind into a tangle and determine a mental illness

From the psychological standpoint, then, we must regard a mental illness as one in which mental causes have produced mental malfunction, and we must, for logical exactness rule out all other pseudo-mental illnesses, such as paralytic dementia. But things are not quite so simple as the position just stated, because, if we are consistent in our reasoning, we must recognise another issue and must be prepared to broaden our definition. We have denied to bodily disease any place in the ætiology of mental disease, for the reason that they belong to different categories both as regards causation and location But if mind is the sum total of the functioning of a whole organism, what is the effect on such functioning of disorder of some part of the organism ? We must allow, at any rate in theory, that any disturbance of structure must necessarily involve modification of the total function, and therefore that all bodily disease must have some mental disorder as a correlate To some aspects of this we will return later on For the moment we must consider how much this admission upsets the satisfactory simplicity of the definition It is a matter of proportion and degree If one could express the matter numerically and apply the principles of the differential calculus to this part of psychology, one would be able to show the extraordinary insignificance of a clean pin-prick as an influence in altering mentation The septicæmia that might follow a dirty pin-prick would possess a far higher value, the presence of a tumour in the frontal lobe might rank higher still

From the psychological standpoint therefore, the definition must be modified by the use of some such word as "mainly" or "essentially" or "primarily" on the principle of Touchstone when he said "much virtue in 'if'" A mental disease is then a disorder occurring essentially in the mind of an individual and caused mainly by trauma of a mental nature This can be put in three words The essential quality of a mental illness is that it is a psychogenic psychic disorder

The Philosophical Point of View

Up to the present we have dismissed rather summarily the problem of the relation of mind to matter Although in the main a question for the arguments of philosophy, yet we should give some consideration to the philosophic point of view, both for its own sake and for the light it may throw on our more medical problems In this respect it is interesting to consider the views of Bertrand Russell In a recently published lecture on "Perception" he refers to the glib way in which people speak of mind and matter as contrasted and opposite entities There is, as a matter of fact, no such complete opposition and no clear dividing line between the two, but rather a difference of degree. An oyster, for instance, is less mental than a man The quality of mental-ness has crept in in the transition between the conditions represented by the phrases "There is a triangle" and "I see a triangle" In the latter situation there has been added a subject who has a perception To Russell, perception is at the meeting point between the physical (sensation) and the mental (the addition of meaning)

He discusses the gradation from physical to mental in another way There are public and private objects, defined as public when all can see them, and as private when none but the owner or subject can do so Touch and sight are extremely public processes in this sense, introspection is extremely private Mental processes, especially dreams, are the most private of all Again, the distinction is one of degree What many people can perceive is physical , what only one can perceive, but can locate in a public place, is in his own body and is physiological , what only one can perceive but cannot so localise is purely private and is mental

In his "Analysis of Mind" Russell deals with this problem much more exhaustively and comes to the same general conclusion, that there is a difference, but that it is not an absolute difference, but rather a gradation through degree of difference The main distinguishing feature is the system of causal laws that each obeys both mental and physical being merely different modes or groupings of one neutral ultimate stuff Things grouped in such a pattern that they obey physical laws are material those that obey psychological laws are mental The whole tendency, nowadays, is for physics to become less material while psychology adopts a more material tone

---

* Paper read before the Medical Section, British Psychological Society

It is interesting to note that the general trend of this philosophical attitude gives support to the conclusions resulting from a psychological approach There is a mental illness and there is a physical illness and they are essentially different both in cause and location, yet there is no absolute line between the two but a gradual shading from physical through partly mental to purely mental Consideration of our subject from the medical aspect will lead to the same general conclusion

The Medical Point of View

There are two ways in which the physician is interested in mental illness, the clinical and the administrative In the former he is concerned with disease processes and their effects on the individual, and with therapeutic measures whereby he hopes to help the patient to recover In the latter he is concerned with the conduct of an institution and with social and legal matters This is not medicine in the true sense, and it is from the former and truly medical point of view that we must now consider our problem From this aspect we deal with individual people, men and women who are ill and it is our business to understand their present suffering and the cause of that suffering, so that we may discover means of relief

The study of the ætiology and pathology of mental illness is an essential though difficult part of our work Failure to attempt it is scientifically slovenly and leaves us as mere empiricists In the past and even now to a considerable extent, much of such treatment as is given for mental illness is little more than empirical Most of it is harmless, some may be helpful but the rest cure sea voyage, change of air, potassium bromide intestinal purification, and similar prescriptions are not informed by any sound knowledge of the real nature and ætiology of mental illness

It is for these reasons of scientific accuracy, and of ultimate efficiency, that we should form and hold some clear idea of what we mean when we speak of mental illness Let us review some of the ordinary conditions with which we are called upon to deal and consider what we can learn from them in answer to our problem

There is more than one set of views on the classification of mental diseases but we can avoid entanglement in these smaller problems by keeping our argument on as broad a basis as possible The mental disorders from which patients suffer do group themselves out into a number of fairly definite and well-recognised units or systems These are sufficiently well defined to be classed as disease syndromes even if they are not actual disease entities in the full sense Let us consider them in the light of the suggested definition

(*To be concluded*)

RED CROSS ACTIVITIES IN THE AMERICAS

AN account of the second Pan-American Red Cross Conference, which met in Washington this summer, appears in the September issue of the *World's Health* At the congress 16 of the 18 official delegations representing the Red Cross Societies of the American continent came from Central and South America and spoke either Spanish or Portuguese as their native tongue The number of medical men among the delegates was a convincing proof of the sympathy which unites the medical profession to the Red Cross Prof Juan de Dios Villegas-Ruiz, President of the Venezuelan Academy of Medicine, acted as chairman of the session devoted to health activities, and the special committee on health, which was elected to study technical problems, was presided over by Dr Paz Soldan, professor of hygiene in the University of Lima (Peru) In the course of the various sessions devoted to the discussion of health topics in their relation to Red Cross work, many interesting sidelights were thrown on Latin-American problems The organisation of public health work in the Central and South American Republics being still in its early stages the field of activity open to the Red Cross is almost unlimited In several of the countries the National Red Cross Society is regarded as the leading unofficial health agency, and in all of them there is close coöperation with the official health departments The Presidents of the Argentine and Brazilian Red Cross Societies are also the directors of the Army Medical Service, while the President of the Chilian Red Cross was formerly the Minister of Health In Cuba the Director of the Health Service is a prominent Red Cross official and the leading Peruvian delegate to Washington is professor of hygiene in the University of Lima

Among the papers read was one by Prof Villegas-Ruiz, of Venezuela, on the importance of eugenics to public health. He emphasised three points (*a*) The desirability of a pre-matrimonial medical certificate (*b*) The importance of child welfare (*c*) Mental hygiene The appeal of M Antonio las Heras Hervas, the blind president of the International Committee of the Blind, drew attention to the incidence of blindness in Latin-America In the 21 Central and South American Republics there are he estimates approximately 115,000 blind persons and in the whole of this vast territory only ten inadequate institutions exist to care for them, whilst not one periodical or book is published in Braille The population of the whole of South America approximates that of the United States, but the former has twice as many blind citizens The speaker appealed to the Red Cross to use its influence on behalf of the blind by making a statistical survey of eye diseases by conducting intensive propaganda on the subject of hygiene of the eyes, and by fighting the causes of blindness Prof Paz Soldan of Peru spoke of the role of the Red Cross in popular health education, which should be simple and objective

Housing Problems in Brazil

Another branch of public health was touched upon by Dr Amaury de Medeiros of Brazil who read a paper on the Red Cross and workmen's dwellings In South America also there is a housing problem, and the familiar difficulty occurs of the dearth of cheap houses owing to the fact that building small houses for renting is not an attractive commercial proposition Dr Amaury de Medeiros described a housing scheme he had carried out at Recife capital of the province of Pernambuco, in his capacity of Director of Public Health Most of the existing houses there were nothing more than huts of palm and corrugated iron and were extremely insanitary He raised $30,000 by public subscription bought a piece of ground, and erected model workmen s dwellings These he let at reasonable prices and with the proceeds, after deductions for repairs, he proceeded to build more houses This scheme has proved most successful The houses have served as models for many private builders and the standard of domestic hygiene among the tenants has risen considerably The speaker appealed to other Red Cross Societies to include housing schemes among their health activities

Health Education through the Conscript

Surgeon-General Julio R Garino, President of the Argentine Red Cross and Director of the Army Medical Service showed how the work of the Argentine Army Medical Service contributed to the health of the Republic and the prevention of social scourges The Argentine conscript receives instruction in hygiene from the moment he enters the army, and the 30 000 conscripts who annually undergo military training return to their homes equipped to become health propagandists in civilian life Vaccination against typhoid, para-typhoid and small-pox is obligatory in the Argentine army and in all military stations antityphoid vaccination is given free of charge to civilians requesting it A careful health record of each recruit is kept from the day he enters The laboratory work carried out by the Army Medical Service and the statistics kept by it have been of great value in completing a medico-geographical survey of the Republic, determining the malarial zone and making a study of the climate soil and disease conditions

The Colombian delegate gave an interesting account of the Health Centre founded in Bogota by the Red Cross in 1921 and now in charge of Dr Adriamo Perdomo

Panama —Bolivia —Paraguay

In Panama the Red Cross is doing good work in child welfare and also for the tuberculous, for whom a clinic is maintained According to the latest reports, over 60 000 children have been registered in the Red Cross child welfare centres since this work was started under the supervision of Señorita Morales In April, 1925, a prenatal clinic was established under Dr Luis C Prieto At present there are 15 child welfare visiting nurses, in addition to one for the prenatal clinic and another who goes daily to see poor families registered in the department for poor relief maintained by the Red Cross Largely owing to the work being done under Señorita Morales's direction, the infant mortality rate in the town of Panama has fallen from 237 per 1000 in 1917 to 138 in 1925 The Panama Red Cross also does good service in visiting the Palo Seco Leper Asylum and helping the lepers in many ways

Bolivia is another country which is much concerned with child welfare, for it suffers from a high infant mortality-rate, that for La Paz being 330 per 1000 in spite of its favourable climate This high infant mortality has been ascribed to an insufficient and impure milk-supply Although the Bolivian Red Cross was only officially recognised in 1923 it has already been active on behalf of children, and has worked in coöperation with the Infant Welfare Society of La Paz

In Paraguay the Red Cross works in close coöperation with the doctors of the Public Health Service, who give their services voluntarily at its milk stations The Red Cross also assists in carrying out school medical inspections and runs some public baths

The resolutions passed by the Conference range over almost the whole public health field, and include recommendations regarding child welfare, eugenics, prevention of blindness, the health of the school child, the teaching of health in the schools, popular health education, housing, industrial hygiene, nutrition, and public health nursing

THE HEALTH OF A TREATY PORT

WEIHAIWEI

THE territory of Weihaiwei was leased to Great Britain by China by a Convention signed at Peking on July 1st, 1898, "in order to provide Great Britain with a suitable naval harbour in North China and for the better protection of British commerce in the neighbouring seas" The leased territory is situated in the Chinese Province of Shantung It comprises the Island of Liukung, all the islands in the Bay of Weihaiwei, and a belt of land ten English miles wide along the entire coastline Mr W Russell Brown, the officer administering the Government, has prepared a report on the affairs of the territory for the year 1925, which has been issued from the Colonial Office Amongst other items it mentions that Surgeon-Commander A McCloy, R N, terminated his appointment in December as M O H for Liu Kung Island, and was succeeded by Surgeon-Commander N S Meiklejohn, D S O, R N

The general health of the civilian foreign community, both resident and visiting was good, and no epidemic occurred One civilian death was recorded from carbuncle of the neck, and there was only one serious case of dysentery —a visitor who contracted the disease before arrival The health of the native population was also satisfactory, only 156 cases of dysentery and diarrhœa were treated, of which 55 applied at the Island Hospital and 30 at Wen Chuan Tang The total attendance at the three hospitals was 15,058, as compared with 14,898 in the previous year, whilst the in-patients treated numbered 259, as against 278 The operations performed were 938, of which 165 were under chloroform and 44 under cocaine, the remainder comprising tooth extractions (368), abscesses, and other minor surgery Forty-two obstetrical cases were attended, mostly in the patients' own homes Tuberculous disease of bones and joints is quite common, and a number of long cane deck chairs have been obtained from Hong-Kong to give these patients the benefits of sunlight and fresh air The seven deaths in the Civil Hospital comprised three from injuries, one from poisoning (suicide), one from cholera, one from amputation of the leg, and one following operation for the removal of a stone in the bladder

Owing to the prevalence of cholera in Shanghai that port was declared infected on August 17th, and all vessels arriving therefrom were boarded and the passengers and crew medically inspected, while a special hospital was fitted up for the reception of any cases that might be landed here Sporadic cases of the disease occurred in neighbouring ports, but only one case reached Weihaiwei and was admitted to hospital, where the patient unfortunately died from uræmia five days later Quarantine was removed on Oct 5th Seventy-three cases of poisoning were treated at the hospitals, arsenic and phosphorus (matches) being the usual poisons employed, the former in attempted murder cases and the latter in the much more frequent attempts at suicide A case of considerable interest was that of a young man whose skeleton was found nine days after he had disappeared from home The whole of the soft tissues had been stripped from the bones, and these were scattered over a clearing in high grass, all the small bones being missing, while the ends of the long bones showed evidence of having been gnawed The skull had a long fracture on the left side, and torn fragments of clothing showed extensive blood-stains on the collar-bands and left shoulder and sleeve, while a blood-stained sack was also found on the spot There was reason to believe that the man had been murdered and his body removed, with the sack over his head and chest, to the place where it was found outside the village, and had there been devoured by native dogs, but it was not found possible to secure a conviction, though three men were charged with the crime

A vaccination campaign was held in May and June and 7074 persons were treated, but small-pox still occurs sporadically in the more scattered districts during the winter and early spring Kala-azar, a disease first identified in 1900 and believed to be conveyed to man from the dog by fleas and bugs, is very prevalent in the district, no less than 100 new cases having presented themselves for treatment during the year The aldehyde blood-serum test was found of value in confirming the diagnosis, and these cases have been treated with success by intravenous injections of antimony tartrate, commencing with a dose of ½ gr, 438 of these inoculations were given during the year

Situated on the sea-shore in the north temperate zone, Weihaiwei experiences neither extreme of great heat or cold The climate is healthy and bracing in winter, and the summer, although hot, is by no means relaxing The highest temperature yet recorded in the history of the territory is 99° F in 1922 and the lowest 1° F in 1913 The heaviest rainfall was 47 70 inches in 1914 and the lowest 15 53 inches in 1918 Rain fell last year on 54 days, the total fall being 23 66 inches, as compared with an average of 26 565 inches during the 20 years 1906–25

SANOCRYSIN IN BELFAST

EXPERIMENTS carried out with sanocrysin in Belfast during the year 1925 by Dr Andrew Trimble, and summarised in his annual report just issued, have led him to the following conclusions (1) Sanocrysin is a distinct therapeutic advance in the treatment of tuberculosis in definitely selected cases (2) Observation for at least a year will be necessary in order to ascertain whether the good results obtained will be permanent (3) Sanocrysin is not suitable for general use, and should be used only in institutions equipped with the necessary apparatus, and under the control of physicians of sufficient experience and expert knowledge in the treatment of tuberculosis (4) Further research is necessary to determine the class of case most likely to benefit by this method of treatment, the correct dose for individual patients, the intervals between the doses, the length of the whole course of treatment, and the indication for the discontinuance of the treatment

PLAGUE AND THE FLEA

Surgeon C L Williams, of the U S Public Health Service, in the *Military Surgeon* for August, makes it clear that the flea responsible for transmitting plague from rat to rat and from rat to man is usually *Xenopsylla cheopis* Some places in the track of plague epidemics escaped in a way unexplained until L F Hirst showed that at Colombo, which plague had then never attacked, the common flea was *X astia*, and *X cheopis* was absent When plague did occur there later, in relation to a special importation of grain, it was in a restricted area of the town, and *cheopis* was now found in that district Madras has also escaped plague, among hundreds of fleas from Madras examined by Hirst all were *astia* Differentiation between *cheopis* and *astia* is difficult, depending on the form of the spermatheca examined under the microscope Hirst's theory got little support until Major F W Cragg, I M S, examining rat fleas from all parts of India to find the habitat of the three main species, *X cheopis*, *astia*, and *brasiliensis*, satisfied himself that the occurrence of plague in an area was closely correlated with the prevalence there of *X cheopis* In our own ports, judging by the experience of Cardiff (THE LANCET, 1925, i, 1051), *cheopis* is not found on rats outside the port area It is probable that when it can be made, a map of *cheopis* distribution will outline the area of plague distribution, as a map of *Aëdes* distribution outlines the yellow fever areas Surgeon Williams asks the question why plague reappears in an area it has once left, and answers it by assuming that at the close of an epidemic rats carry plague as a septicæmia without symptoms, as goats carry Malta fever During 17 months after a recent Galveston epidemic, the last nine rats found infected showed no naked-eye sign of the disease, and the bacilli isolated had but little virulence Men, too, may carry plague bacilli of low virulence in chronically enlarged glands At a favourable opportunity these less virulent bacilli may light up a new epidemic

HYGIENE FOR SCHOOLS

A SMALL text-book[1] on hygiene, which is designed as a health reader for schools, has reached us It is easy to read and understand and covers most of the ground fairly On the anatomical side the skeleton, muscles, blood, heart, &c, are described, chapters on food, digestion, excretion, and the sense organs deal with physiology Chapters on ventilation, clothing, and infection represent the field of hygiene proper The book is open to criticism The treatment of indigestion, for example, need find no place in a volume of this nature, advice as to the use of bicarbonate of soda for "heartburn," is surely quite out of place An outline of infant feeding is rightly included, but there is no mention of the practical application of the study of vitamins discussed at length some pages previously, to artificial feeding The use of dried milk is not mentioned, although condensed milk is condemned On certain controversial matters, such as infantile vaccination and the "tendency" to tuberculosis, Miss Shuttleworth is too dogmatic in her statements The most serious fault of the book, however, is in the absence of any reference to the reproductive system It is essential if a sane outlook on sex matters is to be established, that this system should receive the same attention in elementary text-books as any other system The subject requires delicate handling, but that is scarcely an adequate reason for omitting it in a book written by one who as biology mistress at a girl's secondary school, would seem specially qualified to deal with it

A Plea
FOR DRASTIC REFORMS IN THE TEACHING AND PRACTICE OF MIDWIFERY.

A Paper read before the Section of Obstetrics and Gynæcology of the Royal Society of Medicine

By G. W. THEOBALD, M.D. Camb., M.R.C.P. Lond., F.R.C.S. Edin.,
PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY, BANGKOK,
FORMERLY ASSISTANT MASTER, THE ROTUNDA HOSPITAL, DUBLIN, LATE OBSTETRIC TUTOR IN THE UNIVERSITY OF LEEDS

There is a growing consciousness, which is not confined to medical circles, that the state of midwifery in this country is not what it should be. The official statistics are dreadful. Four women die out of every thousand who give birth to children. That is to say that, assuming that a mother has four children, she undergoes a total risk of 1 in 70 of dying as a result of childbirth. Such figures are terrible, but they only represent a fraction of the truth.

Of the 3000 mothers who die annually in England and Wales over a thousand die from sepsis. If a thousand die, there is little doubt that a great many more are severely infected and barely escape with their lives. There is reason to believe that the actual number who die is greater than recorded, as those women who die within a short period of childbirth, and are registered as dying from pneumonia, should really be included in the deaths from sepsis. A large number of the gynæcological conditions requiring operation, including most of the ectopic gestations, with the risk to life and the long period of disability involved, are made necessary by bad midwifery. A far greater number of women suffer ill-health and varying degrees of inconvenience, often amounting to pain, all their lives, but either cannot bring themselves to face the ordeal of a gynæcological examination or consider that such discomfort is the heritage of all mothers. The numbers of these sufferers is enormous.

Finally, we may consider the sum total of misery, the broken homes, the orphans, the widowers. What more need be said to prove that the cold figures of the Registrar-General only give a very faint idea of the ghastly results of childbirth in England and Wales?

In order to improve matters various steps have been taken. The midwives have been registered. Antenatal clinics have been formed in a large number of centres. There has been an alarming increase, more far-reaching than is realised, in the State control of midwifery. The medical officers of health, with little or no experience of practical obstetrics, have enormous powers and are practically responsible for the control of midwives. A vast amount of money and effort have been expended, and there is very little cause for congratulation. In fact, the figures do not show that amount of improvement which could reasonably have been expected even if such efforts had not been made. There is indeed reason to believe that further improvement is not likely, but rather a disimprovement may be anticipated in the future. The midwife is expected to know too much, and a midwife who knows too much is a danger to the community. A highly educated and trained sister in any of the operating theatres of our great hospitals would not dream of opening a superficial abscess, and yet a woman with less advantages in surgical and other training is expected to make a vaginal examination, to deliver breech presentations, and, in what she considers an emergency, remove a placenta.

The doctor is getting less experience in normal midwifery, and will not be so good at abnormal work as the old practitioner, who learned his obstetrics after he qualified by being an assistant in a large midwifery practice. Lastly, the antenatal clinics, with all their potentialities for good, may in fact be a source of danger, for they have made possible an enormous amount of meddlesome operative midwifery.

There is one solution to the problem which has not been given a fair trial, and that is an improvement in the teaching of midwifery. I am convinced that radical and obvious changes in the teaching of midwifery would be of more value than all the other efforts put together in reducing maternal injuries and mortality, and far less expensive.

PRESENT-DAY PRACTICE OF OBSTETRICS

The following is a short résumé of some of the cases admitted to a maternity hospital during 1925, and may give some idea of the way in which obstetrics is being practised. Practically all of them were admitted, treated, and recorded by myself.

Case 1.—Primipara, aged 25. Labour said to have started five days before, since when she had had about five minutes' sleep. Unsuccessful effort at delivery with forceps. Patient admitted to hospital worn out, the head high, and the external os only one-quarter dilated. Morphia and scopolamine were given and the head later came down and was lifted over the perineum with forceps. Vagina torn to ribbons. Doctor thought that he "was pulling bone against bone damned hard," and he was. Ten stitches. Not morbid.

Case 2.—11-para, aged 42. Practitioner changed a face presentation to a vertex, and tried to deliver head with forceps. Head was high above brim, and the obstruction was caused by the placenta; version; living child.

Case 3.—3-para, aged 31. Doctor applied forceps for an hour or so and then sent for another doctor. Attempts at delivery were made lasting for five hours. The woman was ultimately brought into hospital. The forceps were applied and delivery was fairly easy. The vagina was torn to ribbons. The patient had a severe parametritis and was in hospital for eight weeks, running a temperature up to 104° F. She went out and still is a physical wreck.

Case 4.—Primipara, aged 33. In labour 24 hours. Head above brim. One doctor put on forceps and pulled hard. He then sent for another doctor who pulled hard. The patient came into hospital with the head high and in a seriously collapsed condition. She was given some scopolamine and later some morphia, and the head came down to the perineum and was lifted over with forceps. The vagina was torn to ribbons. The mother ultimately recovered and the child did well.

Case 5.—Primipara, aged 35. Primary uterine inertia. No sleep for five days; frequent vaginal examinations. On admission the head was not engaged by its greatest diameter. Morphia; scopolamine; quinine; forceps; Walcher's position. Female child, 7 lb. 10 oz.; did well.

Case 6.—Primipara, aged 27. The forceps were applied one evening, and after long efforts at delivery had failed the woman was left. Next morning the forceps were again applied, but in vain; and so the woman was admitted to hospital. A baby weighing 8 lb. 14 oz. was delivered by the forceps, and did well (forceps in middle strait).

Case 7.—Primipara, aged 21. Brought in by doctor in his own car for immediate Cæsarean section. The head was well engaged. An injection of morphia and scopolamine was given. A living baby weighing 7 lb. 8 oz. was born in six hours.

Case 8.—2-para, aged 31. Doctor came to hospital to see a Cæsarean section, but the baby had been born spontaneously three days earlier and soon after the mother's admission.

Case 9.—3-para, aged 29. Sent in as a case of obstructed labour, after prolonged efforts at delivery with the forceps, and still under the anæsthetic. An enema was given and a catheter was passed, and a child weighing 7 lb. 10 oz. was born in 12 hours.

Case 10.—Primipara, aged 20. Membranes ruptured 12 hours before admission. Doctor tried to *dilate up cervix nine hours* after the membranes ruptured while the patient was under an anæsthetic, but failed and sent her into hospital as a transverse presentation. By abdominal examination it was found that the head was engaged, and no further examination was necessary An injection of morphia and scopolamine was given and an enema The patient delivered herself of a female child weighing 4 lb (Pelvic measurements 10 in., 10¼ in, 7¾ in) Temperature 102 4° F Pulse 106 before delivery, normal after Two doses of 40 c cm antistreptococcal serum

CASE 11 —Primipara, aged 20 Sent in as a transverse lie Head engaged by abdominal palpation. Scopolamine gr 1/150 Female child weighing 6 lb 12 oz, born in five hours, and did well

CASE 12 —Primipara, aged 26 Forceps were tried on two separate occasions On admission, head just engaged, cervix only half dilated Scopolamine gr 1/150 Head came down on to the perineum and was lifted over with the forceps Baby had been dead for some hours "I have three pairs of forceps—and I used two different pairs and I pulled damned hard and could not shift the head"!

CASE 13 —Primipara, aged 27 Patient sent in as a case of obstructed labour There was a large mass of fæces in the colon Enema, morphia Two doses of scopolamine Two doses of pituitrin Head came down on to the perineum and was lifted over with the forceps Female child weighing 6 lb 14 oz Did well

CASE 14 —Primipara, aged 25 In labour for 24 hours before admission Seven vaginal examinations were made outside On admission the external os was only one finger dilated, but the head was well engaged Morphia, two injections of scopolamine, quinine gr 10 The head came down to the outlet and a male child weighing 6 lb 2 oz was delivered with the forceps and did well

CASE 15 —Primipara, aged 30 Forceps slipped twice Two vaginal examinations by midwife Easy delivery with the forceps Free bleeding from vaginal tear which extended to the fornix Male child weighing 6 lb 13 oz Did well

CASE 16 —Primipara, aged 27 In strong labour for 48 hours Numerous vaginal examinations by midwife Head high above the brim True conjugate 2½ in. and perforation Death from sepsis on nineteenth day Temperature 102 8° F Pulse 120 on first evening!

CASE 17 —Primipara, aged 24 Membranes ruptured six days Labour commenced 24 hours before admission. Doctors out all morning and afternoon Several anæsthetics Cervix manually dilated Patient sent in as a case of impacted shoulder On admission, temperature 100° F, pulse 140, very shocked A case of hydrocephalus Died from sepsis after fighting for her life for eight weeks Temperature started first day

CASE 18 —Primipara, aged 32 Patient was three hours under an anæsthetic while two doctors tried at intervals to deliver with the forceps Head high Pelvic measurements, 8¼ in, 9½ in, 7 in Perforation Mother not morbid "If only I had had a pair of forceps that were long enough and strong enough I would not have brought her in here My wretched things kept bending"

CASE 19 —Primipara, aged 24 In labour 24 hours Membranes deliberately ruptured by midwife Innumerable vaginal examinations Double pneumonia, empyema Patient just escaped with her life

CASE 20 —Primipara, aged 35 In labour 30 hours Cervix only one-quarter dilated Head high above brim Attempts at forceps delivery for two hours Perforation

CASE 21 —Primipara, aged 20 In labour 24 hours Three vaginal examinations by midwife Hydrocephalus Perforation

CASE 22 —3-para, aged 30 Contracted pelvis In labour 24 hours Unsuccessful forceps outside Head above brim Version Living child which did well

CASE 23 —3-para, aged 26 In labour 24 hours Numerous vaginal examinations Sent in as a breech It was a case of prolapsed arm and cord and a living child weighing 7 lb was delivered as a breech—after an internal version had been performed

CASE 24 —4-para, aged 35 The doctor had discovered a prolapsed cord He therefore attempted to deliver with the forceps and failed He sent for another doctor, who also failed The woman was sent into hospital late at night as an urgent case But the baby was born in the taxi-cab

CASE 25 —A case of hydrocephalus The doctor pulled with the forceps for hours They slipped off on many occasions In hospital the skull was perforated without any anæsthetic and the body was easily led out with American bullet forceps

CASE 26 —6-para, aged 27 Miscarriage Arm pulled off and patient sent to hospital, where she delivered herself spontaneously

CASE 27 —7-para, aged 35 Placenta prævia Plugged with two lumps of cotton-wool the day before admission.

CASE 28 —5-para, aged 38 Placenta prævia Marginal. Woke up in pool of blood two days before admission Nurse told her there was nothing to do and she had better get on with her work Temperature 99 2° F Pulse 112 on admission

CASE 29 —7-para, aged 27 Placenta prævia Twenty-six weeks + Very collapsed and anæmic Had been plugged by doctor two days before admission, but she had coughed out the plug almost at once I requested the doctor not to plug again before sending her in, as he had suggested

CASE 30 —3-para, aged 36 Antepartum hæmorrhage for 24 hours She was told that she was a very rare case with her "heart in her bowels" Very ill and collapsed on admission

CASE 31 —11-para, aged 42 Toxæmic Antepartum hæmorrhage. Albumin +++ Numerous vaginal examinations by doctor and midwife before admission.

CASE 32 —11-para, aged 40 Incomplete abortion. Temperature normal Pulse 92 Three tampons in the vagina

CASE 33 —Bleeding for two days One tampon in vagina. Accidental hæmorrhage Albumin +++

CASE 34 —6-para, aged 23 Miscarriage five days before admission Frequent attempts at removal of placenta Finally sent to hospital with the placenta still retained and died within 12 hours of her admission

CASE 35 —2-para, aged 37 Placenta prævia centralis (term) Started to bleed six days before admission. Seven vaginal examinations Acute sepsis Death

CASE 36 —4-para, aged 39 Central placenta prævia. Vagina plugged with 36 in of gauze

Many cases of toxæmia were kept unrecognised for days before being sent into hospital One patient, booked as in-patient for delivery, was kept at home for 15 days because she was too ill to be moved She then came into hospital to die in a few hours At least nine women died during the year as a direct result of sheer bad midwifery It is obvious that for every one case admitted to the hospital after unsuccessful attempts at forceps delivery, there were several women whose children were dragged from them, dead or alive, through half-dilated cervices Nearly every case sent in by a doctor had previously been vaginally examined on several occasions by the midwife

FAILURES IN TEACHING

There can be no shadow of doubt that the doctors and midwives were directly responsible for those and many other similar cases that occurred in the area served by this hospital, and there is no reason to believe that the state of affairs is any better or any worse there than it is in any other industrial centre In the late war, the old lady who invested her money in war loans was morally just as much responsible for the killing of an enemy soldier as was the soldier who fired the rifle, and, in my opinion, the universities and teaching authorities are, if anything, more responsible for the bad midwifery than are the units who actually misapply the forceps The truth of this contention was very forcibly borne in upon me by the following experience

One of the above-mentioned cases was admitted with the head high and the cervix one half dilated The doctor who had sent her in telephoned to me that evening to know what had been done I explained that I had given some scopolamine as the cervix was not yet fully dilated He got rather annoyed with me and said that he was a strong man and had pulled hard, and was certain that the head could not come down The head did come down to the perineum I unwisely wrote inside the chart "The second case of damnable midwifery of the meddlesome type that has been admitted in the last two days" The doctor visited his patient, read the chart, and asked if he could see me He was exceedingly nice and said frankly that he did not know anything about midwifery He had qualified in the last three years, and had had no clinical instruction in midwifery The patient had made a lot of noise and he felt he ought to do something He was amazed to hear that the head came down and promised never again to apply the forceps until the cervix was fully dilated I have discussed this subject with many doctors and they all admitted that they had to learn whatever midwifery they knew—at the expense of their patients

There is one other important consideration Many practitioners in the provinces, rightly or wrongly, are very unwilling to send patients into hospital as they consider that they know as much about midwifery as do the members of the hospital staff, who are themselves very often engaged in general practice

Looking at the matter from another angle How is it possible for the doctors to know anything about the subject? The students attend a lot of lectures, which may or may not be more valuable than reading books They may even get a certain amount of bedside teaching—so-called clinical instruction They do not, however, receive the one thing that is necessary It is of no use to tell a man in a lecture that he should not apply the forceps until the cervix is fully dilated It is necessary for a man to be very sure of himself to refuse to apply the forceps, in the face of pressure from the husband and relations, after a woman has been in labour for some hours He wants to do something, he is expected to do something, and he is not sufficiently experienced and confident to exercise masterly inactivity, that virtue which is of great price He must be shown while a student how such cases are treated. A person living in, or close to the hospital, should demonstrate the treatment of such cases at frequent intervals, and the fact that the woman can in 95 per cent of cases deliver herself. He should be taught the use of such drugs as scopolamine and morphia He should learn that 95 per cent of cases in labour can be conducted by inspection together with Pawlik's grip The resident medical officer is, in most cases, far too inexperienced to conduct this teaching He is, in fact, in many cases afraid of the labour ward sister, and realises that she knows more about normal midwifery than he does It is no exaggeration to state that a man only begins to realise that he knows nothing about midwifery after he has lived for a year in a maternity hospital

DEFECTS OF THE PRESENT HOSPITAL SYSTEM.

Here is the crux of the matter, and it is in the solution of this problem that the hope for the improvement of midwifery lies It is the present hospital system—not the universities, not the specialists, not the practitioners, and not the midwives—that is responsible for the bad midwifery in this country The hospital system of this country evolved in its present form when medicine and surgery were the only two subjects worthy of consideration An attempt has been made to graft the new plant of obstetrics into the old stem, and it is a failure It is possible for a surgeon to say, "I will operate at such and such a time to-morrow," or for the physician to do his rounds at a stated time. The surgical and medical maladies persist for some hours, if not days, and the student is thus able to learn all that is possible about the diagnosis and treatment of the conditions from those best able to teach But it is not possible for the obstetrician to say, "I will apply the forceps at 11 o'clock to-morrow," or "I will do a version for placenta prævia to-night" The conditions in midwifery are all emergencies, and the teacher and his student must reside in or close to the hospital This fundamental difference between obstetrics and surgery or medicine has not been sufficiently appreciated Until there are several combined gynæcological and maternity hospitals in the country, where men can stay and learn midwifery and gynæcology under some teacher—for at least three years—improvement cannot be anticipated The hospitals must be combined, for no man can afford to stay three years doing nothing but midwifery, and then start to learn gynæcology

ORGANISATION OF THE ROTUNDA HOSPITAL

Let me give a short account of the Rotunda Hospital The hospital is managed by a Master who holds his appointment for seven years, and two assistant Masters who hold their appointments for three years and are directly responsible to the Master The extern department is managed by two extern assistants, who are responsible to the assistant Masters and through them to the Master and give the anæsthetics in the hospital No man can be appointed as extern assistant until he has done a six months' course in midwifery, either as a student or post-graduate No man can be appointed as assistant Master until he has been extern assistant No man can be appointed as Master unless he has been an assistant master The assistant Master does one month on the maternity side and the next month on the gynæcological side All the work in the hospital is done either by the Master or his assistants All the records are carefully kept by the assistants, who actually do the operations

If the results in the treatment of placenta prævia are better in Dublin than anywhere else, it is not because the Irish women are more hardy, but because it is not considered justifiable to leave the treatment of such a dangerous condition to a person with very little experience—any more than it is right to leave the treatment of a perforated gastric ulcer to a house surgeon If there are less Cæsarean sections in the Rotunda Hospital, and less cases in which labour is induced, it is not because St Patrick chased contracted pelves out of Ireland, but because those who treat the cases live in the hospital and do not decide in a hurry what treatment to adopt They are content to watch the process of labour at frequent intervals In a most illuminating address on the Renaissance of Midwifery, Dr H R Spencer stated that Boer, the founder of the great Viennese school, studied with Smellie and Hunter and adopted the British practice, "having learnt in France what Art, in England what Nature, could do"

THE RESIDENT OBSTETRICIAN

I am afraid that in many centres in England to-day Nature is not having much of a chance The system by which there are a large number of honorary members on the staff of one hospital makes it impossible for a definite and consistent line of treatment to be carried out for any number of years It is, moreover, almost impossible for the staff thoroughly to supervise the nursing and internal management of the hospital The result is that arrangements, which should be under the control of the obstetricians, pass into the control of the matron and nursing staff I am convinced that a low maternal morbidity-rate can only be obtained if a thoroughly well-trained and competent doctor lives in the hospital and makes it his business to supervise every detail of the routine, such as the cleansing of bed-pans and douche-pans, and the methods adopted for normal deliveries and normal vaginal wash-ups

The students in England very often deliver fewer cases than the nurses, and are taught by people who have had very little opportunity of learning conservative midwifery I myself have many friends with little or no experience of practical midwifery who have been appointed to the staffs of maternity hospitals It is impossible to learn midwifery through being appointed to the staff of a hospital The result is a perfect orgy of Cæsarean sections The reports of the maternity hospitals offer testimony of these facts Worse than that—if a man through obtaining a surgical qualification, is appointed gynæcologist to some hospital he becomes ipso facto an obstetrician A cynic could say hard things considering that the work of a gynæcologist is to repair the effects of bad midwifery I plead, therefore that there should be three or four improved Rotunda hospitals in England —not only maternity hospitals but schools of midwifery—where students can reside and learn practical conservative obstetrics by osmosis The future doctors will then learn not to interfere with normal labour, and to send abnormal cases into some institution where there will be somebody fully qualified to treat the abnormality It is surely reasonable to claim that no operation, other than low forceps delivery, should be carried out in a private house In the maternity hospital to which the cases above described were admitted the forceps were only applied on 50 occasions in 1505 deliveries, including a large number of cases sent in from outside, and in all but 17 cases the head was at the outlet

Midwives and their Functions.

The training of midwives also needs changing I would suggest that they should be forbidden ever—under any circumstances—to make a vaginal examination. If the case is normal no vaginal examination is necessary If the case is abnormal a vaginal examination is strongly contra-indicated The midwife can find out if the head is engaged by abdominal palpation If the patient is bleeding the case is obviously abnormal If it is desired to find out the dilatation of the cervix it can be done with ease by rectal examination In a book recently published rectal examinations were condemned on three grounds (1) The gloves cannot be sterilised after such an examination (2) There is a risk of damaging the walls of the rectum (3) Nothing can be made out The first two reasons need not be discussed The third is equally untenable In the above-mentioned maternity hospital during 1925 all the cases were conducted by rectal examinations After the nurses had made their prescribed vaginal examinations they made rectal examinations, as did the students I claim that it is almost as easy for a nurse to find out all that she wants per rectum as it is per vaginam No emergency case was admitted during the year which had not been examined vaginally on many occasions by the midwife before the doctor was called Nurses are expected to know a lot of theory, and are forced in examinations to say that they would do all sorts of operations in an emergency I know one nurse who was driven to say that she would remove a placenta manually, and then plug the uterus, using a poker! She passed first of all the candidates They are forced to carry an apparatus for giving vaginal douches, which are never indicated during labour, and are allowed to give such a dangerous drug as quinine I have seen one fatal case of rupture of the uterus following quinine

The fundus was not controlled during the third stage of labour in any case during the year 1925 in the maternity hospital of which I am speaking Only two placentæ needed to be manually removed No cases of post-partum hæmorrhage required any intra-uterine douche or manipulation If the midwife practises in a very lonely spot I would suggest that she should receive a special licence to remove the placenta if necessary I would, however, claim that it is a very unwise thing to give uneducated women the right to remove a placenta, to carry out an operation for which they are not trained, and an operation which is by no means easy, is rarely indicated, and is always risky

Sepsis

I have the temerity to suggest that it is an unfortunate fact that the committee of the British Medical Association who have drawn up the interim report on the Causations of Puerperal Morbidity and Mortality have suggested that further progress in the prevention of puerperal sepsis is most likely to be made by the study of the endogenous causation of infection They refer to the exceedingly interesting and instructive paper read by Dr G FitzGibbon and Dr J W Bigger before the Obstetrical Congress in London I have only two observations to make (1) Every case investigated was vaginally examined on at least two occasions by a nurse (2) I do not believe it is possible by any device as yet evolved to get a culture from the uterus that is free from cervical contamination

I have been trying in vain to discover an authentic case of fatal sepsis that occurred in a woman who had never been vaginally examined I certainly have never seen such a case It must be remembered that some methods of normal delivery amount to a prolonged vaginal examination. There can be no shadow of doubt that the vast majority of morbid cases are made morbid by infection introduced from without.

Only 5 1 per cent of the 1505 deliveries during 1925 in the maternity hospital already referred to were morbid, as judged by the British Medical Association standard Of the normal deliveries numbering some 1200, only 30 were morbid by the Association's standard, and of these 30, 18 were morbid on not more than three occasions A midwife would have had to report only 12 cases as being morbid All cases admitted to this hospital from outside after operative interference were given 40 c cm of antistreptococcal serum This serum was given in 76 cases In 57 cases the puerperium was normal, in 3 cases morbidity was noted on four or less than four occasions, while in 12 cases the morbidity was of longer duration There were 4 fatal cases

The Attainment of a Low Morbidity

This is, I think, the lowest morbidity that has ever been claimed by any maternity hospital in the British Empire, and I consider it due to (1) the minimum of interference during delivery, (2) the free use of 1–1000 biniodide of mercury throughout the hospital, (3) the abolition of all binders, so that the patients were free to sit up in bed within 12 hours of their confinement; (4) free purgation (every patient received 2 oz of castor oil the morning after her delivery, and some purgative every night she was in hospital), (5) the serum given to contaminated patients There can, I think, be little doubt that this serum is of great value in preventing sepsis from occurring, if it is given soon enough and in large enough doses Once the patient is septic it appears to be absolutely valueless A marked serum rash was noted in a few cases, and a rather severe anaphylactic reaction occurred in one patient It is clear that if the serum is to be given at all it should be given in moderately large doses, and it is to be hoped that it will soon be offered for sale at a much lower price The serum was not given to any non-contaminated patient, however severe the operation

This low morbidity was obtained in spite of the fact that the hospital is badly constructed, and more than 80 patients were often housed, although there was only proper accommodation for 50 beds I have often seen more than a dozen patients sleeping on mattresses on the floor Puerperal sepsis is not caused by bad surroundings but by bad midwifery

The Control of the Perineum

In an effort to get further back to Nature I requested the sisters to allow 100 women to deliver themselves, by themselves, while the nurse was standing at a distance from the bed This was termed the Garden of Eden method of delivery and gave the following results —

	No	Perineum intact	Perineum lacerated.
Primiparæ	35	18	17
Multiparæ	65	62	3

Two hundred cases were then delivered by the modified Garden of Eden method All the nurse did was to prevent the head from being born with a flop The results were as follows —

	No	Perineum intact	Perineum lacerated
Primiparæ	80	63	17
Multiparæ	120	116	4

The woman is allowed to get into any position she chooses There is no feeling for the cord, there is no lifting of the leg, causing the woman to feel exposed, and there is no possible contamination of the nurse's hands with the contents of the bowel

This method, while interfering with Nature as little as possible, gives results which are as good if not better than any ritual for the control of the perineum.

STERILISATION OF GLOVES.

There is one more subject on which I should like to touch Some two years ago Dr Bigger and I read a paper before the Royal Academy of Medicine in Ireland showing that gloves could be sterilised by washing with soap and water, using a scrub-brush if necessary, and then immersing the gloved hands in 1–1000 biniodide of mercury for half a minute Nobody has disputed the truth of these contentions, but some have said that the doctrine is dangerous At the present moment the vast majority of midwives in practice get fæces on their hands every day and make vaginal examinations without gloves Boiling destroys the rubber and the midwives cannot afford to keep buying fresh gloves If the gloves are washed and treated with the care that is bestowed on a crêpe-de-chine camisole they will last for a long time I contend that it is much safer for a midwife to use gloves so sterilised, and not to make vaginal examinations, than to make vaginal examinations with her bare fingers which cannot be sterilised Fæces are gross dirt and can be easily washed off, and they are often less harmful than the discharges of the vagina which may not have an offensive odour

Moreover, it is impossible for a doctor to apply the forceps or to clear out an abortion single-handed in an antiseptic manner unless he adopts the method I have suggested There is no need for a sterilised drum to conduct midwifery with safety In the series of cases here described I neither used nor allowed the assistant to use any sterile towels in the delivery of such cases as might have to be treated in a private house

CONCLUSION.

The results in midwifery in England and Wales are bad, and are a lot worse than the figures would suggest The solution of the problem lies in a return to Nature and in better midwifery This desired result can only be obtained by drastic changes in the teaching of midwifery. I suggest that the whole attitude towards midwifery be altered and that (1) nurses be forbidden to make vaginal examinations, (2) nurses be forbidden to deliver breech presentations, (3) nurses be forbidden to control the fundus during the third stage; (4) that the modified Garden of Eden method of delivery be adopted, or, anyhow, that methods involving much vaginal manipulation be forbidden, (5) that binders be abolished, and free drainage during the puerperium be obtained, (6) that several large combined gynæcological and maternity hospitals be instituted on the lines of the Rotunda Hospital; (7) that the student should spend much less time watching operations he will never perform, and a great deal more time watching normal labour while living in a maternity hospital There is no need for him to spend more time at gynæcology

The efforts at improvement during the last 20 years have failed The general public are getting alarmed There is, I fear, a strong probability that a State medical service may be forced on the profession, and the bad state of midwifery may be a strong argument in its favour

When I reflect on the care, skill, team-work and money expended in the operating theatres of our land in patching up broken men and women, and reflect on the inadequate training which allows men to kill and cripple women in their prime women who are performing the act for which they were created; when I consider the sum total of misery which is daily mounting through bad obstetrics when I realise that the country of Simpson, Lister Smellie, and Hunter is no longer mentioned in the literature of obstetrics, I feel constrained in all humility to make a plea for radical changes in the attitude towards midwifery and to hope that these changes will be made by the profession before unnecessary and ill directed control is exerted by the State

SUBCUTANEOUS FIBROID SYPHILOMATA

A RARE MANIFESTATION OF LATE SYPHILIS

BY C WORSTER-DROUGHT MD CAMB,
MRCP LOND,
ASSISTANT PHYSICIAN TO THE METROPOLITAN HOSPITAL, TO THE WEST END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, AND NEUROLOGIST TO BETHLEM ROYAL HOSPITAL

THE condition for which Parkes Weber[1] in 1920 suggested the name "subcutaneous fibroid syphilomata" is admittedly a very rare manifestation of late syphilis Indeed so scanty is the literature of the subject that Goodman[2] on reporting a case in 1921, claimed that only two such cases had previously been recorded, and further that when he and Young[3] published a case in February, 1920, there was at that time no similar case in the literature.

In the case here described, bilaterally symmetrical lesions involved the ulnar nerves and yielded rapidly to antisyphilitic treatment

Description of Case

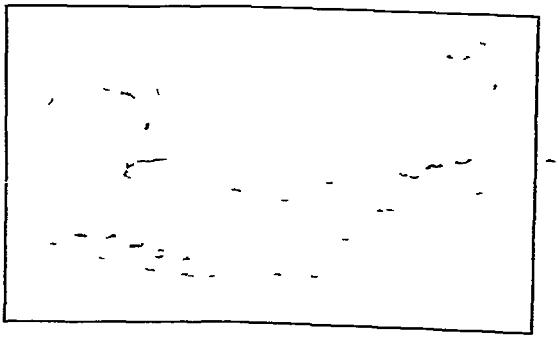
The patient is a woman, aged 27, married three years, no children and no history of miscarriage She has had a slight goitre since the age of 14, and at 12 years had an attack of diphtheria, otherwise no previous illnesses She gives no history suggesting acquired syphilis

Family History —Her father died at the age of 67, having suffered for over 12 years from a condition the patient terms "creeping paralysis," the description of which suggests tabes dorsalis (intense pain in legs, unsteady gait, and loss of control of bladder) Her mother, still alive, has had epileptic fits (average frequency one per month) since the age of 15 An elder sister died at 30 with Graves's disease, one brother, aged 35, has a goitre, and three elder sisters are healthy

History of Present Condition —The patient states that during the past three months small lumps have developed on the inner and posterior aspect of both forearms, they first appeared just below the elbows and gradually spread downwards towards the wrist At first the lumps were quite painless, but more recently she has had neuralgic pain

Condition on Examination —A series of hard subcutaneous nodules extend downwards along the inner aspects of both forearms from just below the olecranon to a point three inches above the styloid process of the ulna The nodules are bilaterally symmetrical and diminish progressively in size from above downwards, those nearest the elbow being the largest and varying from 1 to 2 cm in diameter At the lower end of the series the lesions have a diameter of only a few millimetres (Fig 1 is a semi-diagrammatic representation of the condition which did not show well in a photograph) The nodules are quite hard and adherent to the deeper tissues the skin over them however, is freely movable The majority are quite painless on palpation and only a few situated within an inch or so of the upper limit of the series on each side give rise on firm pressure to tingling pain referred to the little and ring fingers In the deeper tissues of the upper third of the forearm, just anterior to the ulna and in the region of the ulnar nerve some small nodules can be felt, pressure on these also produces pain in the distribution of the ulnar nerve Over the ulnar area of each hand there is some hyperalgesia to pin-prick. The interossei hypothenar and adductor pollicis muscles, however, show good voluntary movement and react normally to faradism There is some parenchymatous enlargement

FIG 1

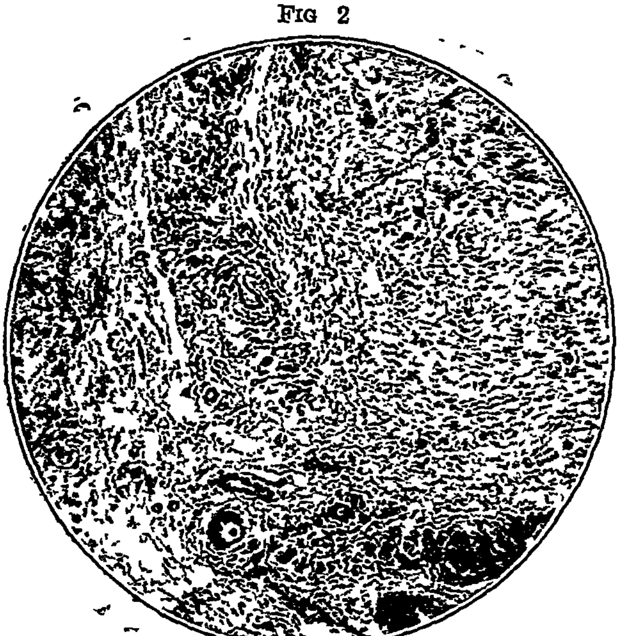


Semi-diagrammatic representation of condition of patient of the thyroid gland with pulse-rate of 76 and no signs of hyperthyroidism All other systems show no abnormal physical signs

X ray examination of the forearms reveals some nodes on the periosteum of the ulna on both sides, but not corresponding to the nodules seen and felt in the tissues

Pathology —To determine the diagnosis of the condition, one of the nodules a short distance below the elbow was excised and submitted to Dr Clement Lovell for histological examination The report was as follows "The small tumour, which is tough and elastic on section, is a gumma Sections stained with hæmotoxylin and Van Giessen stain show, on microscopical examination, masses of fibrous tissue separated by a looser tissue which is highly vascular The vessels in this latter area are surrounded by aggregations of inflammatory cells, chiefly small round cells Some of the vessels show thickening of the intima with very little infiltration of the vessel wall, other vessels show thickening of the adventitial coat with marked infiltration by small round cells" (Fig 2). The blood serum yielded a positive Wassermann reaction

FIG 2



Section of syphiloma (× 70) showing fibrous tumour surrounded by a zone of inflammatory tissue In this zone are many vessels showing endarteritis obliterans with periarteritis

Subsequent Progress —The patient was given six intravenous injections of novarsenobillon (two doses of 0 45, two of 0 75, and two of 0 9 g) alternating with six intramuscular injections of mercury cream (1 gr of Hg per dose), one injection being given each week Potassium iodide (gr 10 t d s) was also taken by the mouth By the time the fourth injection of novarsenobillon was reached all pain had disappeared, and there was a remarkable diminution in the size and consistency of the nodules When the last of the series of injections had been given no nodules were visible, and all that could be felt was a slight induration of the subcutaneous tissue at the sites previously occupied by the nodules When seen six months later there had been no recurrence, and it was even difficult to be sure of any degree of tissue thickening

Subcutaneous Syphilomata. General Clinical Description

The age incidence varies between 27 and 60 years in the recorded cases and both males and females are affected (three males and six females) The lesions consist of nodules varying in size from that of a pea to that of a chestnut The most frequent site is the ulnar border of the upper part of the forearms, the larger nodules being placed near the olecranon, and in distribution they are, as a rule, remarkably symmetrical The nodules may also be found in the region of the knee, particularly in relation to the ligamentum patellæ, between the patella and the anterior tuberosity of the tibia, more rarely they extend downwards towards the ankle Those occurring in the lower limb are usually larger and less firm and hard than those in the upper limb. In character the nodules are of fairly regular rounded or oval shape and of a peculiar wooden hardness, a most unusual feature of gummata They are themselves painless, and it is only when they lie in relation to a nerve, as in the case reported above, that any pain is experienced The skin overlying them is freely movable, but they are usually adherent to deeper structures X ray examination, when performed, has shown no bony changes, in my case, however, there were nodes on the periosteum of the ulna which did not correspond to the nodules felt in the tissues. The lesions develop slowly, attaining a maximum size in a period varying from a few months to two years in different cases, and then remain stationary

Their *syphilitic* nature is proved by the presence of a positive Wassermann in all recorded cases in which this test has been performed and also by the histological character of the nodules—viz, that of an organising gumma Microscopical examination shows a *chronic* inflammatory lesion which has become fibrous without undergoing true gummatous or necrotic changes Goodman and Young in their case made from a nodule a preparation by Levaditi's silver impregnation method, but *Treponema pallidum* was not found In most of the cases there has also been a history indicating syphilis—chancre, miscarriages, &c —and, in a few, other signs of syphilis —*e g*, a tertiary syphilide in Goodman's case In my case a congenital origin is possible, the history suggesting that the patient's father had suffered from tabes dorsalis In those cases treated on modern antispecific lines the nodules disappeared

Summary of Cases Previously Recorded

1 Goodman and Young's case[3] Woman, aged 29, married No history of syphilis, one abortion at the fourth month and no subsequent pregnancies Wassermann reaction positive Bilaterally symmetrical nodules extending downwards from two inches below the olecranon to the styloid process of the ulna, also a single mass over left knee and in the ligamentum patellæ Duration eight years Microscopical diagnosis Granuloma, probably syphilitic

2 Parkes Weber's case[1]. Man aged 60 Gonorrhœa at age of 20, but no history of syphilis Wassermann reaction positive Multiple subcutaneous nodules present on legs, chiefly right and extending downwards from just above the knee to the ankle, in addition, one nodule was situated on the outer side of middle of right thigh Duration seven years The condition was associated with peri-urethral induration of the penis (induratio penis plastica) and also old disseminated choroido-retinitis of right eye Microscopical diagnosis. Tertiary syphilitic lesion become fibrotic.

3 Goodman's case[2] Man aged 36 History of chancre ten years previously, but no secondary symptoms W R. positive Two nodules were present on the right forearm below the olecranon and three on the left forearm, the first of the latter was symmetrical with those on the right side, the second was situated over the internal condyle, and the third two inches above the olecranon On the left leg a smaller nodule was present over the tubercle of the tibia. Duration eight years Over the metacarpal of right thumb there was also a serpiginous tertiary syphilide 2 × 1¾ in Microscopical diagnosis of nodule Gumma The tumours disappeared following treatment with 12 intravenous injections of arsphenamine, the less recent leaving only a slight induration

4 Howard Fox's case[4] Negress aged 45 No definite history of syphilis, two children in good health and two miscarriages W R strongly positive. Nodules on both forearms along ulnar borders and also in the region between patella and tuberosity of tibia on both knees Duration two years Microscopical diagnosis Organising gumma. The lesions responded slowly and imperfectly to intravenous injections of arsphenamine, but the patient attended at only irregular intervals

5 In the course of his communication, Howard Fox mentions another case which he observed in 1919 Negress aged 34 No history of syphilis, but had three children, all of whom died as infants W R positive Nodules present on olecranon and ulnar borders of both forearms and also on both knees below the patella Duration 13 years Microscopical diagnosis · Unsatisfactory, as piece of tissue was too small and patient was lost sight of

Howard Fox's communication was read at the forty-fourth annual session of the American Dermatological Association, Swampscott, Mass , in June, 1921 In the subsequent discussion the following speakers mentioned that they had met with similar cases

6 T E Lane Man aged 45 Nodules on ulnar borders of each forearm near olecranon The lesions had almost disappeared after six injections of arsphenamine

7 J F Schamberg Two cases in negresses, each showing symmetrical cartilaginous nodules below the elbows

8 J C Fordyce also mentioned a case of nodules on one elbow

Juxta-articular Nodules

The clinical similarity of the tropical condition known as "juxta-articular nodules" to subcutaneous syphilomata was commented upon by Goodman and Young Juxta-articular nodules appear first to have been described by MacGregor and were later, in 1909, studied in detail by Jeanselme[5] They occur in natives of many tropical countries, including Java, Siam, and tropical Africa According to Manson,[6] juxta-articular nodules are round or oval multiple symmetrical nodules, painless and very hard, and increase slowly in size until they may attain the size of a small orange Broden and Bernard's analysis[7] indicate that the nodules are more frequent in the lower limbs than the upper

In his original communication, Jeanselme described juxta-articular nodules as of various sizes, usually globular in shape and often collected together in masses At first they lay deep in the subcutaneous tissues, some freely movable and others appearing to be adherent to the periosteum, from which possibly they originated Later the nodules became more superficial and might be incorporated in the skin Beyond distension and slight discoloration at the highest point the skin underwent no change The nodules were remarkably symmetrical and occupied the extensor aspects of the extremities, with a tendency to surmount bony prominences and to group themselves near joints—e g, in the arms about the olecranon, acromial process, and dorsal surface of fingers, and in the legs about the great trochanter, head of tibia, and external malleolus Microscopically, the nodules were divisible into three zones —

1 External zone of inflammation made up of fibrous tissue, numerous blood and lymph capillaries, plasma and polymorphonuclear cells, and large fixed cells with a fibrillated reticulum.

2 Intermediate transitional zone of gradually homogenising connective tissue which lost its fibrillar structure and stained deeply with eosin

3 Internal zone of degeneration formed of irregular homogeneous and translucent blocks Bacteriological examinations proved negative

Jeanselme considered that the nature of the nodes was not revealed by microscopical examination and that they had no relationship to syphilis, tuberculosis, or xanthoma, nor were they fibromata nor tophi Davey[8] considered them to be a late manifestation of yaws An organism has been claimed by some to be the ætiological factor, but this has been denied by others Thus, Van Dijke and Oudendal (1922–23) and Soberheim (1924) claim to have demonstrated spirochætes in the nodes, Gongerot a fungus which he placed under Nocardia, and Ouzilleau (1913), filarial elements (quoted by H. S Stannus[9])

In 1920 Poupelain,[10] in reporting five cases of juxta-articular nodules, stated that he had found they were rapidly cured by novarsenobillon injections and drew further attention to their possible association with syphilis In the same year Montel[11] described four cases, also responding favourably to novarsenobillon, while in 1921 Da Matta,[12] Noque,[13] Broden and Bernard[7] reported similar cases Foley and Parrot,[14] also in 1920, in reporting 21 cases of juxta-articular nodules, drew attention to the presence in their cases of specific lesions, a history of abortions or of infant mortality and in some the presence of a positive W R In many of the cases mercurial treatment also proved efficacious In the following year these authors[15] recorded a further case showing a partially positive W R

Cange and Argaud[16] also in 1921, in reporting two cases, supported the view that the nodules were syphilitic in origin Their first case was that of a woman, aged 30, who presented symmetrically placed nodules on the posterior surface of the upper third of both forearms, extending downwards from the olecranon. They varied in size from a small nut to an apricot and were hard, mobile, and painless The W R was negative The skin over the area occupied by the nodules showed, it is said, erythematous papular lesions (? specific) Histologically, one of the nodules showed a fibrous tissue growth with giant cells, obliterative endarteritis, and perivascular infiltration of plasma cells Cange and Argaud's second case[17] was that of an Algerian woman, aged 56, who six years previously had acquired syphilis from her husband She developed a chancre on the left labium and later a macular roseola and anal and vulvar condylomata In spite of antispecific treatment, ocular symptoms and nodules developed one and a half years later One nodule was present on each elbow, the lesions being round, very hard, and freely movable under the skin

It would appear, therefore, that there must either be a very close relationship between "subcutaneous fibroid syphilomata" and many of the cases reported as examples of juxta-articular nodules or that in some instances the two conditions have been confused Indeed, cases such as Cange and Argaud's first case appear almost identical with the former condition H S Stannus,[9] in a recent admirable review of the relationship of yaws and syphilis, states that Gutierrez[18] has done well to call attention to the fact that juxta-articular nodules must be differentiated from subcutaneous fibroid syphilomata, which closely resemble them, but can be distinguished histologically To quote Stannus "It appears probable that lack of appreciation of these facts has led many observers . . . to make an incorrect diagnosis, and that a diagnosis unsupported by histological examination in the absence of a history above suspicion must remain a doubtful one Both sets of lesions, so long as they have not reached an advanced stage of fibrosis, respond to treatment by salvarsan"

Syphilitic Bursitis

The possibility of relationship between subcutaneous syphilomata and syphilitic lesions in bursæ has been considered by Howard Fox The whole subject of bursal syphilis was admirably reviewed in 1909 by Churchman,[19] who, in a thorough search of the literature, was able to collect 26 undoubted cases Of the 26, ten presented somewhat similar features to the cases under discussion, and, as H Fox points out, most of the points on which, according to Churchman, the diagnosis of bursal syphilis is based, might apply to some of the cases of subcutaneous syphilomata —viz, history or coexisting signs of syphilis, spontaneous development, slow evolution, symmetrical distribution, absence of pain, and joint involvement In most cases reported as subcutaneous syphilomata, however, the situation of the nodules precludes any connexion with bursæ, and microscopical examination fails to show any tissue resembling that of a bursa

I have to express my indebtedness to Dr Clement Lovell, pathologist to Bethlem Royal Hospital, for the pathological investigations, and also to Dr. E Le Maistre for drawing my attention to the case.

SOME POINTS IN THE PROGNOSIS OF AURICULAR FIBRILLATION *

BY H WALLACE JONES, M.Sc., M.D. LIVERP., M.R.C.P. LOND.,
SENIOR HON ASSISTANT PHYSICIAN, LIVERPOOL ROYAL INFIRMARY

(*From the Heart Department of the Royal Infirmary.*)

IT is impossible to over-emphasise the importance of auricular fibrillation in diseases of the heart, for more than half of the cases dying of heart failure show this abnormal rhythm at some time or other before death. The prognosis in fibrillation, therefore, is of some moment, especially as there are such wide differences in the time lived by patients suffering from this irregularity—some dying within a few hours of the inception of the abnormal rhythm, while others live for many years without any marked impairment of their activities.

The dominant factor in the prognosis is the condition of the heart muscle, and it must be our aim in forming a judgment in these cases to find out as much as we can with regard to its condition. The evidence will naturally group itself into two headings: (1) clinical evidence, (2) electrocardiographic findings.

Clinical Evidence.

The *onset* of auricular fibrillation is always sudden, and in making a prognostic judgment the symptoms which accompany the onset are extremely important, and give valuable clinical evidence of the state of the functioning power of the heart. If the patient is quite unaware when the change from the normal to the abnormal rhythm took place it shows, as a rule, that the heart muscle is fairly good, and the outlook is much more favourable than if the change was accompanied by severe distress and evidence of sudden heart failure, generally of the "congestive type." This sudden heart failure is the result of the inception of the rapid and disorderly action of the heart caused by the fibrillation. When there is much distress at the onset the outlook is grave, and indicates a considerable impairment of the heart muscle—while occasionally the symptoms are so severe that the patient may only survive a few hours.

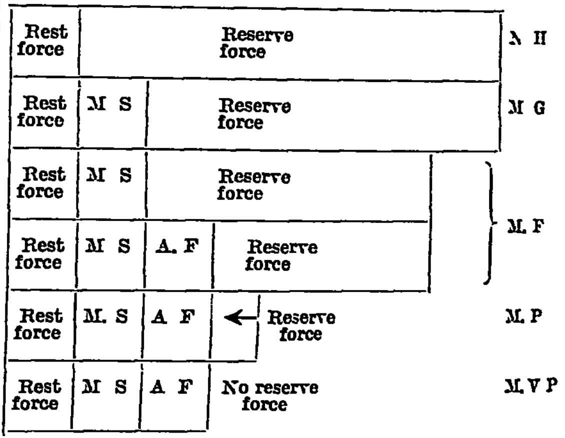
There is one type of auricular fibrillation, however, in which the change from the normal to the fibrillation is not accompanied by marked distress, though the outlook is unsatisfactory, when cardiac failure occurs, and that is the type in which the heart-rate remains persistently slow during the fibrillation when not under the influence of digitalis. In this type there is usually marked myocardial damage, giving rise to delay in the junctional tissues and therefore partial heart-block. The slow rate, with fibrillation, is for a time an advantage for the heart, but when these cases commence with symptoms of cardiac failure the outlook is very bad—as they respond so unfavourably to treatment with digitalis or strophanthin.

Rest Force and Reserve Force.—In order to get a clear idea how this variability in the symptoms is brought about it is necessary to consider the forces at work in the heart.

Mackenzie[1] divided these into "Rest force," or force necessary to maintain the circulation when the patient is at rest, and the "Reserve force" which is drawn upon when any effort is undertaken, however slight.

In the diagram the normal heart is shown with an enormous "reserve force" to draw upon when any effort is undertaken. If mitral stenosis is present the disability of this valvular lesion curtails somewhat the "reserve force," but if the heart muscle is in good condition this limitation is so slight compared with the size of the "reserve force" that the patient is unaware of it. If the "reserve force" is diminished by a damaged heart muscle, the disability imposed by the mitral stenosis becomes more obvious by limiting the response to effort.

Diagram showing "Rest Force" and "Reserve Force," with Auricular Fibrillation



M. S = Mitral stenosis A F = Auricular fibrillation
N H = Normal heart M G = Muscle good M F = Muscle fair M. P = Muscle poor M. V P = Muscle very poor

The onset of auricular fibrillation imposes an additional load at the expense of the "reserve force," and if this is already curtailed considerably by previous damage in some the response to effort becomes much restricted. The fibrillation may entirely use up the "reserve force," causing the symptoms of heart failure to appear when at rest, and these may be so severe that the patient only survives for a few hours; while in other cases after rest and treatment a certain amount of "reserve force" may be regained. After fibrillation has once been established the outlook depends on a number of factors independent of the abnormal rhythm.

The patient's *response to effort* is important and gives as a rule one of the best indications of the functioning power of the heart. Where the response is considerably curtailed, especially when this limitation is rapidly increasing, the outlook is very grave.

Marked *cardiac enlargement* is another unfavourable factor in prognosis, and indicates a considerable myocardial damage in addition to the fibrillation.

The presence of a considerable degree of *valvular disease* also makes the outlook less favourable, and at the same time renders the attempt to establish the normal rhythm with quinidine more dangerous, especially in mitral stenosis.

In fibrillation it is extremely difficult to give a definite prognosis until one has had the opportunity of observing the patient's *response to treatment*. This consists, as a rule, in attempting to limit the heart-rate with digitalis or strophanthin, or trying to convert the fibrillation back to a normal rhythm with quinidine sulphate.

When the heart, uncontrolled by digitalis, is beating at a rapid rate the distress may be considerable, but it does not indicate per se that the ultimate prognosis is grave, if it responds readily to digitalis. Cases in which nausea and vomiting are readily produced by digialis are unfavourable as a rule, especially if tinct opii added to the digitalis or the substitution of Nativelle's granules fail to overcome it. One has then to depend on the intravenous injection of strophanthin to slow the heart-rate, which is rather a difficult method to keep up for any length of time, or the administration of tinct strophanthi by the mouth, which is generally an unsatisfactory proceeding.

Quinidine sulphate, when it re-establishes the normal rhythm, improves the outlook considerably, and the change may remain permanent, but in the majority unfortunately it tends to revert sooner or later to fibrillation If fibrillation occurs during the course of an acute infective disease, such as pneumonia, the outlook is extremely grave and a fatal termination is almost inevitable—the fibrillation in these acute toxic conditions is very resistant to treatment Fibrillation in Graves's disease is, as a rule, a serious complication, and often an adequate response to treatment is not obtained until partial thyroidectomy has been performed

---

* Based on a paper read before the Liverpool Medical Institution

In giving a prognosis in all cases of auricular fibrillation it must be remembered that ventricular fibrillation is liable to occur at any time with, in consequence, sudden death of the patient

Statistics of Expectation of Life in Auricular Fibrillation

I have attempted in this investigation to collect all the cases of auricular fibrillation which have attended the heart department of the Royal Infirmary, and by means of postcards sent out every three or four months, to obtain the expectation of life, from the time of their attendance in the department, with symptoms of heart failure, until their death, using only those cases in which the exact date of death is known

General Cardiac Mortality (All cases attending the department)		*Cases of Auricular Fibrillation* *General Mortality*	
No of cases	870	No of cases	118
„ deaths	119	„ deaths	27
Mortality	13 7 %	Mortality	23 %

Mortality in fibrillation cases almost double the general cardiac mortality

Comparison of the Two Main Groups of Fibrillation, the Rheumatic Type and the Senile Type

GROUP 1 —*Auricular Fibrillation of Rheumatic Origin.* (20 cases)		GROUP 2 —*Senile Auricular Fibrillation* (6 cases)	
Av E L	3 y 6 m.	Av E L	8 5 m
Males	2 y 1 m	Males	5 5 m
Females	4 y 1 m.	Females (1 case)	1 y 11 m

Av E L =Average expectation of life, Y =years M =months

Expectation of life in rheumatic cases nearly five times as long as senile cases

Comparison of Cases of Mitral Stenosis with and without Fibrillation

GROUP 3 —*Mitral Stenosis, with Auricular Fibrillation* (15 cases)		GROUP 4 —*Mitral Stenosis, with Normal Rhythm* (13 cases)	
Av E L	2 y 8 m	Av E L	1 y 10 m
Males	1 y 6 m	Males	1 y 6 m
Females	3 y 1 m	Females	2 y 6 m

Comparison of Cases of Aortic Regurgitation with and without Fibrillation

GROUP 5 —*Aortic Regurgitation with Auricular Fibrillation* (6 cases)		GROUP 6 *—*Aortic Regurgitation with Normal Rhythm* (20 cases)	
Av E L	4 y 9 m.	Av E L	1 y 9 m.
Males	3 y 5 m.	Males	1 y 2 m
Females (1 case)	11 y 4 m	Females	4 y 1 m

* With Wassermann reaction positive the average duration of life in this group was 1 year 5 months

Expectation about twice as long with auricular fibrillation as without

Comparison of Cases of Fibrillation with and without Marked Cardiac Enlargement

GROUP 7 —*Auricular Fibrillation with Marked Cardiac Enlargement* (11 cases)		GROUP 8 —*Auricular Fibrillation without Marked Cardiac Enlargement* (18 cases)	
Av E.L	2 y	Av E L	3 y 7 m
Males (7)	1 y 4 m	Males (8)	3 y 8 m
Females (4)	3 y 3 m	Females (10)	4 y 4 m

Electrocardiograph Findings

In the electrocardiographic appearances of auricular fibrillation Hewlett and Wilson[2] have drawn attention to the fact that there are two main types, the coarse type and the fine type, depending on the size of the fibrillary waves

I have compared the average expectation of life for typical examples of these two types and find that they are approximately equal

Expectation coarse fibrillation (13)	3 y
„ fine „ (16)	3 y 7 m.

Premature beats, of course, always ventricular in type, often occur with fibrillation

Expectation of life with premature beats (5)	4 y 9 m
„ „ in simple auricular fibrillation (5)	3 y 9 m

There is very little difference between them, but it is slightly in favour of the cases with premature beats Willius[3] has suggested that premature beats in auricular fibrillation are an unfavourable sign, but in this series one of the cases with premature beats lived 11 years and two others five years, so that it cannot be a very lethal condition

Influence of Bizarre Q R S on Auricular Fibrillation

Expectation with bizarre Q R.S including one bundle lesion (6)	1 y 4 m
Expectation with simple auricular fibrillation	3 y 9 m

There is marked shortening in the expectation of life, with a bizarre Q R S.

Cases in which there is an inverted "T" and Auricular Fibrillation—In all cases the patients were under the influence of digitalis

Expectation with "T" inverted	3 y 4 m
„ „ simple auricular fibrillation	3 y 9 m

Practically equal

Interpretation of Results

In the interpretation of these results it must be remembered that auricular fibrillation is always a serious disability to the heart, and the apparent contradiction which occurs in some of the groups, where the expectation of life is longer with fibrillation than with normal rhythm, is due to the fact that the cases in this series were taken from patients suffering from varying degrees of heart failure, all sufficiently advanced to necessitate their attendance at a special department In the fibrillating case it is the onset of the fibrillation which has given rise to the symptoms necessitating the patient's attendance at the clinic, while in the other group, the failure with a normal rhythm, the failure is the result of myocardial inadequacy itself, for which treatment is relatively of little value The fibrillating case, on the other hand, can, as a rule, be controlled by the digitalis group—i e, the cause of the cardiac failure can be met with adequate treatment, and in those patients with relatively good heart muscle the outlook is comparatively good †

Conclusions

These conclusions are based on cases with evidence of cardiac failure (1) Auricular fibrillation is of more serious significance in senile than in rheumatic heart disease, (2) in cases of mitral stenosis the presence of fibrillation makes little difference to the expectation of life, (3) in cases of aortic regurgitation the expectation is better when fibrillation is present than with a normal rhythm, (4) the prognosis is better with aortic regurgitation than with mitral stenosis, (5) with marked cardiac enlargement the outlook is more grave; (6) the expectation of life is longer in females than males; (7) in the electrocardiographic findings the presence of a bizarre Q R S is of most significance in the prognosis

---

† In a recent paper published since this communication was read Parkinson and Clark-Kennedy[4] have also drawn attention to this difference in the outlook of fibrillating and non-fibrillating cases, once heart failure has occurred.

CARBOHYDRATE METABOLISM IN DIPHTHERIA

BY FRANCIS J. HECTOR, M D BRISTOL, M R C S ENG,
ASSISTANT RESIDENT MEDICAL OFFICER, HAM GREEN HOSPITAL, BRISTOL

WHILE chronic disorders of carbohydrate metabolism have been very extensively investigated, the causes and consequences of more acute derangements have received much less attention The pathology, both of experimental diphtheria in animals and of diphtheria in man, affords abundant evidence that the diphtheria toxin has a marked effect upon the various tissues which are factors in carbohydrate metabolism—that is, the liver, the pancreas, the kidneys, the thyroid, the pituitary glands, and the chromaffin system In diphtheria we have to consider a metabolic disturbance caused, not by a slow toxæmia or a gradual auto-intoxication of certain gland cells, but by a massive dose of a potent poison such as the diphtheria toxin

Investigations have been carried out upon a number of cases of diphtheria of various degrees of severity and at different stages Cases which bore in their early stages a clinical resemblance to diphtheria but which were afterwards found not to be suffering from this disease were also investigated The following tests were performed.

1 Estimation of blood-sugar (MacLean's method) before and after carbohydrate ingestion

2 Estimation of carbon dioxide in the alveolar air by Fridericia's apparatus

3 Alkali tolerance-test (modification of Sellard's method) All the cases were treated by alkali therapy, receiving per diem, according to age, sodium bicarbonate 4–8 g, potassium bicarbonate 0 6–1 2 g, and calcium carbonate 0 6–1 2 g The reaction of the urine in response to the administration of the alkali was observed

4. Investigation of hepatic metabolic function (Shirokauer's [1] method)

Urinary examinations. (*a*) *Acetone bodies* (*b*) *Acidity* (*c*) Ammonia coefficient

Unfortunately, it was found inexpedient to determine the sodium bicarbonate content of the blood, nor has it always been possible owing to the age or the serious condition of some of the patients examined to carry out the whole of the tests upon the same individual, but this has been done wherever practicable.

Clinical Records of Cases Investigated

CASE 1 —F. C, male, aged 4½ years Admitted Dec 9th, 1924, *on second day of illness He had a thick, fairly extensive* patch of diphtheritic membrane on both tonsils, 30,000 units of diphtheria antitoxin were given. Bacteriological report, positive Up to the time of the test, on the third day of illness, he had vomited once Pulse was 120, first cardiac sound decidedly weak, temperature 98 6°F He was of an ashen colour and there was a fair amount of collapse Diet was 5 oz of milk every four hours, and four hours after last feed blood-sugar was 0 062 per cent, 15 g of glucose were given in 100 c cm. water, and blood was taken at half-hourly intervals for two hours The blood-sugar (Table I) took one hour to reach its apex of 0 181 per cent, and at the end of two hours had only fallen to 0 162 per cent. There was no glycosuria throughout the test. The blood-sugar curve is similar to those obtained in mild early cases of diabetes There is slight delay in absorption, the curve taking one hour to reach its apex (the maximum concentration may have occurred between the taking of the half hour and the one hour specimens) The chief feature, however, is the undue prolongation of the curve, which at the end of two hours is still far above the fasting level This suggests the presence of a definite degree of deficiency in the carbohydrate storage mechanism, although this deficiency is not sufficient to carry the sugar concentration over the renal threshold. This delayed fall is all the more striking when the probable slow rate of absorption is considered Urine contained acetone and aceto-acetic acid Acidity=73 9 (in spite of alkali therapy), ammonia coefficient=1/5

TABLE I II

Time taken	Blood-sugar per cent	
Fasting	0 062	0 081
After 15 g glucose—		
½ hour	0 126	0 175
1 „	0 181	0 143
1½ hours	0 175	0 131
2 „	0 162	0 112

Glycosuria nil

Two days later the child developed slight symptoms of palatal paralysis (which afterwards became very marked) and acute circulatory failure On the tenth day of disease the general condition had greatly improved. Temperature normal, pulse 72 Fasting blood-sugar was now 0 08 per cent and the curve corresponded very closely to the normal (Table II) The storage defect was very small and the rate of absorption normal Urine showed albumin, acetone, and diacetic acid in faint traces Acidity=31 5, ammonia coefficient 1/20

During the time, therefore, that the child was under the influence of the diphtheria toxin there was a definite condition of acidosis, a low fasting blood-sugar, and a definite deficiency of the carbohydrate storage mechanism. Recovery was uneventful and complete

CASE 2 —J G, male, aged 12 years Admitted Jan. 13th, 1925, on second day of illness A fairly severe case of diphtheria with extensive membrane, considerable faucial œdema, greatly enlarged cervical glands, and marked prostration. 40,000 units of diphtheria antitoxin were given. Bacteriological report, positive On the 15th pulse was 120 and temperature 101° F Cardiac sounds of poor quality Fauces still thickly covered with exudate and cervical glands very enlarged Prostration severe The blood-sugar estimations (Table III) showed a marked deficiency of the storage mechanism very similar to that described in Case I There was no glycosuria *Urine contained acetone* and diacetic acid Acidity=41, ammonia coefficient=1/10

TABLE III IV V

Time taken	Blood sugar per cent.		
Fasting	0·075	0·075	0·075
After 30 g —	Glucose	Læval	Glucose
½ hour	0 131	0·075	0 125
1 „	0 187	0·093	0·081
1½ hours	0 175	0 106	0·056
2 „	0 150	0 112	0·056

Glycosuria nil

The following day the symptoms of toxæmia had somewhat abated Temperature 99 5°, pulse 98, 30 g of lævulose were administered, and the blood sugar estimations (Table IV) showed a small increase in the concentration of blood-sugar, which was at its maximum at the end of two hours *Apart from the evidence of storage defect* there is a rise of 37 mg above the first value and, according to Beaumont and Dodds,[2] a rise of 30 mg or more above the original level indicates a degree of hepatic inefficiency

On Jan 29th the general condition was much *improved* Throat clean, cervical glands normal, temperature normal pulse 76 Following 30 g of glucose blood-sugar curve was normal (Table V) Five weeks later patient developed palatal paralysis Recovery uneventful and complete

During the toxæmic stage of the disease Case 2 showed (*a*) acidosis, (*b*) deficient carbohydrate storage, (*c*) slight hepatic inefficiency

CASE 3 —W C, male, aged 24 years Admitted Jan. 31st, 1925, *on third day of illness* with history of sore-throat and vomiting Temperature 100° F, pulse 108 The fauces were very congested and œdematous, with large atypical patches on both tonsils The patient complained of great pain

TABLE VI *VII*

Time taken	Blood sugar per cent.	
Fasting	0 093	*0 093*
After 50 g —	Glucose	Læval
½ hour	0 175	0 118
1 „	0 150	0·086
1½ hours	0 131	0 112
2 „	*0 106*	0 112

Glycosuria nil

Cervical glands were enlarged. *Direct* smear was negative, but the appearance of the throat was so suggestive of a virulent type of diphtheria, *often associated* with considerable œdema, that 28,000 units of diphtheria antitoxin were given Fasting blood-sugar was 0 093 per cent *Following* the administration *of 50 g* of glucose the blood-sugar estimations were practically normal (Table VI.) Urine acetone nil. Diacetic acid, nil. Acidity=38, ammonia coefficient=1/18 On the following day condition was unchanged and lævulose tolerance-test showed a slight interference with hepatic efficiency (Table VII) There was no glycosuria during either test. The bacteriological result of the culture was negative, and as the condition progressed it manifested itself as a case of quinsy and showed no after symptoms of diphtheria. This case was interesting because, although there was considerable intoxication owing to the septic condition of the throat, yet there was no evidence of a disturbance of carbohydrate metabolism such as occurred in the two previous cases

CASE 4 —Of a similar nature to the preceding one was the case of T T, male, aged 28 years Admitted Feb 9th, 1925, on third day of illness Temperature 102° F, pulse 84 Throat congested. Large atypical patch left tonsil Direct smear negative. Diphtheria antitoxin 16,000 units given. The fasting blood-sugar was 0 112 per cent. and the tests showed no departure from normal (Table VIII) The respiratory quotient gave evidence that the carbohydrate was being utilised On the following day the condition had improved somewhat Temperature was 100 5°, pulse 76, 50 g of lævulose were administered This test showed a very definite interference with hepatic function, a slow rate of absorption, and also a degree of storage inefficiency (Table IX) Bacteriological report on culture, negative A typical quinsy afterwards developed

TABLE VIII IX

Time taken.	Blood-sugar per cent	Respiratory quotient.	Blood-sugar per cent.
Fasting	0 112	0 9	0 118
After 50 g —	Glucose		Lævul
½ hour	0 156	1 15	0 131
1 „	0 112	1 2	0 156
1½ hours	0 125	0 9	0 156
2 „	0 106	0 9	0 156

The last two cases would suggest that the tolerance for lævulose is more affected by septic conditions than by the influence of the diphtheria toxin

CASE 5 —R R, female, aged 14 years Admitted Jan. 12th, 1925, on fourth day of illness suffering from severe faucial diphtheria. 40,000 units of diphtheria antitoxin given Marked toxæmia. Bacteriological report, positive On the eleventh day there was palatal paralysis and on the fifteenth day the blood-sugar was estimated before and after 30 g of glucose. The fasting blood-sugar was 0 086 per cent The blood sugar (Table X.) took one and a half hours to reach its maximum and there was a very definite delay in storage The respiratory quotient rose from 0 8 to 1 2 half an hour after the glucose was given, showing that the sugar was being utilised General condition at the time of examination was quite fair, temperature 98 4° F, pulse 96 Urine contained no acetone or diacetic acid Acidity=45, ammonia coefficient 1/14 Four days later the temperature was 98 4° and the pulse 96 Lævulose tolerance-test was carried out and gave no evidence of hepatic inefficiency (Table XI) Fourteen days later blood-sugar following glucose administration was normal and fasting blood-sugar level was raised (Table XII) Subsequent recovery was complete and uneventful.

TABLE X XI XII

Time taken	Blood-sugar per cent	Respiratory quotient	Blood-sugar per cent	
Fasting	0 086	0 8	0 075	0 106
After 30 g —	Glucose		Lævul	Glucose
½ hour	0 150	1 2	0 075	0 175
1 „	0 150	0 9	0 068	0 156
1½ hours	0 168	0 8	0 082	0 118
2 „	0 156	0 9	0·075	0 100

CASE 6 —E B, male, aged 9 years Admitted Feb 10th, 1925, on fifth day of illness with fauces covered with exudate Profuse nasal discharge 30,000 units of diphtheria antitoxin were given. At the time of the glucose tolerance-test (eighth day of disease) patient was in a very toxic condition Temperature 99° F, pulse 100 Urine acetone, and diacetic acid present. Acidity=58, ammonia coefficient=1/7 The blood-sugar tests showed a very marked delay in storage and the respiratory quotient gave no evidence that the sugar was being utilised (Table XIII) The lævulose tolerance was apparently not impaired, but there was again no evidence that the carbohydrate was being oxidised, and the respiratory quotient was distinctly low throughout (Table XIV)

TABLE XIII XIV.

Time taken	Blood-sugar per cent	Respiratory quotient	Blood-sugar per cent	Respiratory quotient
Fasting	0 086	0 7	0 106	0 75
After 30 g —	Glucose		Lævul	
½ hour	0 150	0 7	0 100	0 75
1 „	0 137	0 75	0 106	0 8
1½ hours	0 162	0 8	0 106	0 75
2 „	0 162	0 7	0 106	0 75

CASE 7 —F B, female, aged 11 years Admitted Feb 16th, 1925, on second day of illness Fauces very swollen and covered with exudate Temperature 100 5° F., pulse 100 Ashen colour First cardiac sound weak. 30,000 units of diphtheria antitoxin given Bacteriological report, positive Urine acetone and diacetic acid present Acidity=64 4; ammonia coefficient=1/165

The following day the general condition had slightly improved. Temperature 100 5°, pulse 100 Appearance less toxic Blood-sugar estimations showed a mild interference with storage of carbohydrate (Table XV) The respiratory quotient in this case rose to unity, showing that a certain amount of oxidation of the carbohydrate was proceeding After two hours of the test had elapsed blood was again taken at hourly intervals up to the end of six hours (Table XVI)

TABLE XV XVII.

Time taken	Blood-sugar per cent	Respiratory quotient	Blood-sugar per cent
Fasting	0 086	0 8	0 112
After 30 g —	Glucose		Lævul
½ hour	0 150	0 9	0 131
1 „	0 137	1 0	0 131
1½ hours	0 143	1·0	0 131
2 „	0 112	0 8	0 112

TABLE XVI

Time taken	Blood-sugar per cent	Time taken.	Blood-sugar per cent
Fasting	0·086		
After 30 g glucose—		After 30 g glucose—	
1 hour	0 137	4 hours	0 106
2 hours	0 112	5 „	0·086
3 „	0 112	6 „	0·062

At the end of four hours it had only fallen to 0 106 per cent, and in six hours it had reached 0 062 per cent., which was little short of being a definite hypoglycæmia The lævulose tolerance-test (Table XVII) revealed nothing definite regarding hepatic inefficiency Seven days later palatal paralysis developed Subsequent recovery was complete and uneventful

CASE 8 —D I, female, aged 11 Admitted Feb 21st, 1925, on seventh day of illness in a moribund condition. Temperature 97° F Patient blue and pulseless Fauces completely covered with exudate Profuse sanguineous discharge from mouth and nose 38,000 units of antidiphtheritic serum were given Urine contained acetone and diacetic acid.

(Inj adrenalin m iv)	
4½ hours after 30 g glucose	0·075

Acidity=48 5 ; ammonia coefficient=1/4 9 Immediately after injection of adrenalin m. iv the blood-sugar was found to be 0 075 per cent , 30 g of glucose were given and blood-sugar estimated at one-hourly intervals for four hours Blood-sugar estimations (Table XVIII) show no interference with absorption, but a very definite storage deficiency The final reading of 0 068 per cent was decidedly low An injection of adrenalin m. iv was then given Twenty minutes later the blood-sugar was 0 075 per cent It was impossible in this case to estimate the CO_2 content of the alveolar air Twelve hours later the patient died

Discussion

The first noticeable feature is the low value of the fasting blood-sugar in cases of severe diphtheria The average reading is 0 075 per cent , and the lowest 0 062 per cent .This value was materially increased after the stage of toxæmia had passed In view of the very prolonged fall, which the curve almost invariably shows, 0 062 per cent is probably nearer the true fasting value. In each case the blood was taken at least three hours after the last feed, which would consist of 4–6 ounces of milk, representing approximately 5 5–8 5 g of lactose Table XIX shows the effect of 5 ounces of milk on the blood-sugar in a fairly severe case of diphtheria It is seen that at the end of four hours the blood-sugar is still 6 mg above the original level On account of the condition of the patients it was not deemed advisable to withhold nourishment for more than four hours on each occasion when the tests were performed, nor was this necessary as long as it was recognised that the fasting blood-sugar value thus obtained was probably a little higher than the true one

TABLE XIX

Time taken	Blood sugar per cent
Fasting	0 062
After 5 oz milk—	
1 hour	0 125
2 hours	0 100
3 ,,	0 086
4 ,,	0 068

In none of the cases described was there persistent vomiting, which might be held to account for the low concentration of blood-sugar Case 1 vomited once and the fasting blood-sugar was 0 062 per cent In Case 3 (not a case of diphtheria) there was vomiting on four occasions on the day of the test, and the blood-sugar was 0 093 per cent Defects in the glycogenolytic function of the tissues, particularly the liver, might be the cause of the low blood-sugar, especially when the frequency of hepatic lesions is borne in mind The lævulose tolerance-test for hepatic metabolic efficiency has, on the whole, been negative, but it has given conflicting results with other observers and may be of little practical value It would appear that no really reliable and at the same time harmless test of hepatic metabolic function is at present available Jaundice in human diphtheria is very rare and no records of such a complication exist in this hospital In diphtheria in dogs there is a special tendency to jaundice, however, but there are no observations on the state of carbohydrate metabolism Judging by the lævulose tolerance-test only, the metabolic functions of the liver would appear to be more affected in septic conditions of the throat than by diphtheritic toxæmia

Both in animals and in man the diphtheria toxin leaves many and varied post-mortem traces of damage to the suprarenal glands, and interference with their function may, therefore, be expected Case 8 shows the effect of adrenalin in bringing about an increase in the blood-sugar and suggests adrenal insufficiency as a very likely cause for the low blood-sugar value This is quite in agreement with the extreme asthenia, anæmia, and feeble pulse associated with the stage of diphtheritic intoxication In this regard, it is of interest to note that hypoglycæmia, Addison's disease, and the toxic stage of diphtheria, have some common features In cases of severe collapse in diphtheria, epinephrin, when injected, often causes a marked temporary improvement in the condition It is possible that this improvement may be more directly due, in such cases, to its action on the liver in converting glycogen into glucose, than to its powers as a cardiac stimulant, the latter rôle being filled by the glucose as it is evolved

There is not a great deal of evidence concerning injury to the thyroid gland in diphtheria, but any interference with its function would constitute an additional hindrance to glycogen mobilisation if, as Griffith [3] suggests, this gland acts directly through the suprarenal gland The influence of a possible disturbance of pituitary function must also be considered, since impairment of function of this gland results in a subnormal percentage of sugar in the blood

One of the most constant and definite departures from the normal found in these investigations has been the production following the ingestion of glucose of a blood-sugar curve with an abnormally slow decline, and sometimes a late apex When the latter does occur the assumption that there is some delay in absorption offers a reasonable explanation, and one which is quite compatible with the condition of the patient The prolonged fall, like the low fasting blood-sugar concentration, only occurs during the toxic stage of the disease The reasons for attributing the prolonged fall of a curve to a defect in the carbohydrate storage mechanism receive, on the whole, general acceptance There is, however, another factor to be considered—namely, the condition of acidosis which obtains in these cases The existence of this condition is shown by the carbon dioxide tension of the alveolar air (Tables XIII and XIV), the presence of acetone and diacetic acid in the urine, the high urinary acidity, and the high ammonia coefficient (in spite of alkali therapy) The average time taken to render the urine alkaline by the doses of alkalis previously mentioned was 12 days Peters [4] has shown how profound this condition of acidosis can be in severe cases of diphtheria, persistent vomiting often occurring in the absence of suitable treatment Cammidge [5] and other observers have pointed out the effects on the sugar content of the blood of changes in the acid base equilibrium of the systemic circulation These effects are stated to result in hyperglycæmia and glycosuria, and are not pronounced unless there are associated defects of carbohydrate metabolism Therefore, although the increase in the fixed acids, relative to the bases, of the blood may introduce a disturbing element into the control over the concentration of the blood-sugar, the slow decline of the curve is probably mainly due to a defect in the carbohydrate storage mechanism The importance of the regulating and storage function of the liver and the frequency with which hepatic lesions are found in death from uncomplicated diphtheria would suggest that the liver is chiefly at fault concerning this defect But the effect of the diphtheria toxin is widespread among the endocrine system, and the nervous system is also affected In the present state of endocrinology it is not possible definitely to state what would be the effect on carbohydrate metabolism of diphtheritic lesions of these very intricate systems It certainly would appear that an investigation into the effects of the diphtheria toxin upon the functions of the endocrine system in particular would afford a very interesting and profitable field for research

In Case 6, during the time when there was marked toxæmia and acidosis, the respiratory quotient, besides being low, showed no tendency to advance towards unity after the ingestion of carbohydrate In Case 7 the rise was very small, although unity was obtained, but in this case the condition of acidosis was not so marked In Case 4 and Case 5, where there were no symptoms of acidosis at the time, the respiratory quotient reached 1 2 a half to one hour after the carbohydrate was given These variations in the respiratory quotient are not so marked as some reported by other investigators, but their entire absence in Case 6 and the very slight rise in Case 7 would suggest that the oxidation of carbohydrates is at fault This imperfection in carbohydrate metabolism would, of course, lead to the presence in the blood of those acids which are intermediate products in fat katabolism The vomiting which may follow this ketosis completes a vicious circle, the vomiting causing starvation, and the lack of nourishment further aggravating the ketosis In the ketosis of toxæmia of pregnancy and of post-operative "acidosis," if ample carbohydrate can be administered by the rectum subcutaneously or intravenously, the ketosis may be checked, the vomiting cease, and feeding by mouth may be resumed It would appear as if the failure of the power to utilise the blood-sugar initiated the ketosis and that a vicious circle supervened, causing the symptom-complex to persist This cycle may be broken by controlling the vomiting so that food may be given and retained, but the ideal treatment would be the administration of glucose in such a way that it could be utilised. Since there appears to be, in diphtheritic toxæmia, a difficulty, or even inability, on the part of the tissues to utilise glucose, the suggestion of Thalhimer[6] seems of great value Thalhimer suggests that the injection of insulin following the introduction into the blood of a sufficient amount of glucose would overcome this metabolic inefficiency. It is proposed in this hospital to treat experimentally by this method a series of suitable cases of diphtheria as they present themselves If by this treatment the tissues can be provided with the means to utilise glucose, which is the ideal substance for counteracting any tendency to acidosis, then the danger of the toxic stage of diphtheria would be very materially lessened Singularly, few observations are available concerning lesions of the pancreas in death from uncomplicated diphtheria, but the evidence of the respiratory quotient suggests that pancreatic function may be impaired Even in diabetic necrosis the pancreas is often quite normal macroscopically, and careful microscopic examination frequently fails to reveal any histological changes

The hypoglycæmic symptoms which follow an overdose of insulin show how sensitive is the nervous system to a grave metabolic disturbance, and it will be of prime interest to notice whether an attempt to assist or stabilise carbohydrate metabolism in diphtheria will have any good result on the paralytic sequelæ which are so characteristic of this disease

Conclusions

1 That in cases of severe diphtheria, during the stage of toxæmia and acidosis, carbohydrate metabolism is disturbed and unstabilised (*a*) The concentration of the fasting blood-sugar is abnormally low (*b*) There is a marked defect in the storage mechanism (*c*) The ability of the tissues to utilise glucose is diminished

2 That this disorganisation of carbohydrate metabolism passes away with the stage of diphtheritic intoxication

3 The cause of the metabolic disorder is probably to be found in interference with the functions of the liver, the endocrine glands, and the nervous system through the action of the diphtheria toxin

My thanks are due to Dr. B A. Peters, senior medical officer, Ham Green Hospital, Bristol for permission to investigate these cases and to publish the results

A NOTE ON

DOSAGE IN PHOTOTHERAPY.

BY ALBERT EIDINOW, M B, B S LOND

(*From the National Institute for Medical Research*)

EXPERIMENTS carried out recently indicate that the normal skin is sensitive to sources of light which emit ultra-violet rays shorter than 3100 A U.[1] The skin exposed to any such source of light responds after a latent period of time by an erythema, on which may follow desquamation and pigmentation It has been shown that the degree of erythema produced depends upon · (1) the distance of the skin from the source of light; (2) the temperature of the skin; (3) the kilowatt energy of the source of light and intensity of ultra-violet rays shorter than 3100 A.U. emitted, (4) the individual sensitiveness of the skin to light

From a series of observations on the effects of "ultra-violet radiation" of the skin,[2] it was shown that doses of light which produced erythema increase the non-specific bactericidal power of the whole blood for a period varying from 1–4 hours after the exposure to light There is some evidence[3] of a preliminary stage of depression of the hæmobactericidal power half an hour after exposure The following table gives an indication of the results obtained .—

	Average percentage hæmobactericidal power before and after exposure of skin to mercury-vapour lamp	
	Before	After
Rabbit	35	100
Pig	66	93
Dog	58	91
Man	83	100

From observations on about 180 consecutive patients who were undergoing light treatment, it was shown that the exposure of the skin of the chest and back to the mercury-vapour lamp or arc, which subsequently resulted in erythema, often increased the bactericidal power of the blood An attempt was made to determine the minimal erythema dose of light by previously testing the sensitiveness of the skin[4] In all these cases, and also in the animal experiments, the total surface area of skin irradiated was chosen in an arbitrary manner It has been shown that excessive exposure of the skin to light is a harmful procedure Colebrook[5] found that such exposures may diminish the bactericidal power of the blood But in all these observations stress has been placed upon the ultra-violet or light dosage and not on the area of skin exposed The experiments described in this paper have been carried out to determine the importance in phototherapy of the surface area of skin irradiated.

General Procedure

The skin of a number of rabbits was exposed to the mercury-vapour lamp (M V L.) and the bactericidal power of the blood was determined before and after irradiation The animals were all carefully weighed before the experiment, and the surface area of skin which was exposed to the source of light was controlled and measured At each experiment the dosage of light was estimated by measuring the intensity of ultra-violet rays emitted according to the lethal action on infusoria[6] By these means it was possible to calculate the smallest area of skin per kilogramme of weight of the animal, which after exposure to the M V L produced a definite increase in the bactericidal power of the blood By carrying out a similar series of experiments the importance of the surface area of skin exposed to dosage—i e , length of time of exposure—was observed

A Typical Experiment

The abdomen of six rabbits was shaved by means of soap and a razor The animals were carefully weighed A sterile blood specimen was collected from each animal (by bleeding from the left ear vein), and the blood was defibrinated with a sterile glass rod The animals each in turn were fastened and irradiated, after being covered by a large piece of cardboard having a central perforation in it corresponding to the surface area of skin chosen for irradiation The source of ultra-violet rays was either a water-cooled M V L (2 5 amps +200 volts), applied locally to the skin, or a M V L (2 5 amps +110 volts between electrodes), 3 in distance from the skin The lethal time for infusoria, or I K units, under these conditions was 3 minutes, so each 3 minutes' exposure corresponded to one I K unit The following plan of procedure was adopted in this experiment

A second sterile blood specimen was collected two hours after the irradiation of the skin and was defibrinated as before The bactericidal power of each sample of blood collected was determined by the method described by A E Wright, L Colebrook, and E J Storer [7]

TABLE I —*Summary of Results*

Rabbit No	Wt in grammes	Area of skin exposed to M V L	Area of skin exposed per kilogm wt	Time of exposure	I K units	Average percentage hæmobact Before radiation.	Two hours after radiation	Increase
		sq cm	sq cm	mins

23	1610	49 0	30 4	60	20	65	90	+33
24	2480	49 0	19 8	6	2	75	93	+18

Conclusions —1 A definite erythema was seen over all the skin areas irradiated, and a marked œdema of the skin of rabbits Nos 19 22, and 23 was seen the following day These three animals later showed desquamation, and a scab formed at the site irradiated 2. In animal No 19 the small skin area irradiated did not produce a decided increase in the bactericidal power, in spite of the massive dosage

Method of Recording and Classifying the Experimental Results Obtained

By these means a series of experiments were carried out in which the surface area of skin exposed to the source of light and the length of time of exposure was controlled In the first series of experiments a very small surface area of skin was exposed For this purpose the water-cooled M V L (K B B) of the Kromayer type was employed, and the light was applied locally to the skin The diameter of the circular patch exposed was 4 0 cm and the surface area was therefore approximately 12 6 sq cm The length of time of exposure was varied from 5 to 30 minutes (2–6 infusoria killing units) In no case could any definite change in the bactericidal power of the blood be observed in this series of experiments Following this, other experiments were carried out in which a gradual increase in the area of skin irradiated and variation in the length of time of exposure were made In all about 120 animal experiments were performed The results of these experiments were grouped together and classified according to the surface area of skin irradiated per kilogramme weight of the animal Each of these series was again classified into similar series according to the time of exposure, expressed in terms of I K units An average of the results of each similar group of experiments was recorded as the final average result obtained The initial bactericidal power of the rabbit's blood, tested against staphylococci, has been found to vary from 30 to 60 per cent , the extent of the increase in the killing power of the blood subsequent to exposure of the skin to ultra-violet light would, therefore, depend upon the initial value of the blood In these experiments the increase in the hæmobactericidal power was expressed in the following terms —

$$\frac{a^2—a^1}{a^1} = \text{Increase in killing power of blood}$$

when a^2 = bactericidal power two hours after radiation
a^1 = bactericidal power before radiation

Conclusions from Experiments

From this series of experiments the following observations have been recorded —

1 An "erythema" dose of light is necessary to obtain an increase in the bactericidal power of the blood after radiation of the skin

2 In all the experiments in which the minimal erythema dose of light was employed—i e , 2 I K units (*a*) The smallest areas of skin from 1–5 sq cm per kg of weight were subminimal and failed to give a "bactericidal" response (*b*) Areas of skin from 5–10 sq cm per kg were the minimal area which had to be irradiated, to show a definite increase in the bactericidal power of the blood (*c*) Areas of skin from 15–20 sq cm per kg showed a more decided improvement in the bactericidal power of the blood after irradiation (*d*) The areas of skin from 20–50 sq cm per kilogm wt showed the optimal response. (*e*) Areas of skin over and above 50–100 sq cm per kilogm. wt of the animal did not give any bactericidal response and appear to be too large a surface area irradiated

3 When the length of time of exposure is increased so as to produce a greater degree of erythema and œdema of the skin (*a*) On the whole, provided an erythema dose was maintained, no very striking changes other than those already mentioned was observed (*b*) The subminimal areas exposed showed no change (*c*) A slight improvement was seen in the minimal areas—i e , 5/10 and 10/20 sq cm. per kilogm wt (*d*) No rise was seen in the experiments in which large area and intense dosage were employed In some cases a decided fall in the bactericidal power was recorded

4. There therefore appear to be two great factors which control the bactericidal response of the blood to irradiation of the skin (*a*) The surface area of skin irradiated per kilogm wt of the animal. (*b*) The intensity of the erythema produced—i e , the length of time of exposure, &c

In all these experiments the surface area of skin irradiated per kilogm wt of the animal appeared to be the more important factor than the time of exposure or the intensity of ultra-violet rays, provided the erythema dose was maintained Some observers maintain that the biological action of light is in part due to the production of a photo-chemical substance, derived from either the tissue cells or the blood cells, but no definite experimental proof supports this view It is conceivable that an excess of such a substance would inhibit the efficiency of the leucocytes. In many cases of severe sunburn, and also with burns caused from heat and other causes, the surface area of skin irradiated plays an important role in the sequelæ which may follow. It is possible to produce "sunstroke" by irradiating the head with an intense focused beam of visible light, but this effect is due to the penetration to, and the heat effect on, the brain of the visible rays Conversely, it is difficult to seriously damage small animals which have been made "light sensitive" by means of eosin or hæmatoporpyhrin unless a large area of skin is exposed to the source of light

---

[7] THE LANCET, 1923, i , 417, 473

Observations on Human Cases.

It is of interest to correlate the surface area of skin exposed per kilogm wt of the animal to that of the human body. In the case of a person weighing 10 st this roughly gives the following results :—

	Area Sq cm per kilogm wt		Sq in		In. (approx.)
Subminimal area	1–5	=	56	or	7 × 8
	5–10	=	112	,,	11 × 10
Minimal area	15	=	168	,,	12 × 14
	25	=	280	,,	17 × 17
Optimum area	40	=	448	,,	21 × 21
	50	=	560	,,	26 × 26
Maximal optimal area	80	=	896	,,	30 × 30
	100	=	1120	,,	33 × 33

The subminimal area would therefore be 56 sq. in, the optimum area from 280 to 560 sq in, and the maximal optimal area over 896 sq in.

Since these experiments have been carried out, the effect of radiation of the skin on the bactericidal power of the blood has been investigated in over 30 patients who were having light treatment In all these cases the skin of the back extending to the level of the last rib (or 1–2 in below) was exposed to the M V or to the arc lamp In the great majority of cases an increase in the killing power of the blood was observed with a minimal erythema dose of light These results compared favourably to those obtained previously when the skin of the chest and back was irradiated It is beyond the scope of practical clinical methods to carefully weigh patients and measure areas of skin: but exposure of small areas of skin, such as the back or chest, have shown good results In the present method of treatment the skin of the body is roughly divided into four areas: (1) the back, (2) the chest, (3) the front of the legs, (4) the back of the legs One of each of the areas is exposed to the source of light every alternate day. The dose of light employed is always the minimal erythema dose The aim of each treatment consists in the production of a mild erythema which disappears within 48 hours and may be followed by desquamation The patient has three treatments per week, so that an interval of rest of at least nine to ten days elapses between the exposure of any one of the four areas of skin This interval of time allows for the skin to completely recover from the previous dose of light. In this way the skin will be found to remain sensitive and react to small doses of light and an erythema can be usually maintained with 2–3 I K units As a usual routine treatment is started with the mercury-vapour lamp With the onset of a slight perceptible pigmentation (this is often seen after the second exposure of each area) the dosage with the M V.L is increased, or treatment is started with the arc lamp In those cases where failure to develop a definite erythema occurs the dose of light is repeated over the same area of skin and increased In no case is any area of skin irradiated which shows signs of desquamation, the skin is always rested until it appears to be normal. By means of this technique the area of skin exposed to the source of light is proportional to the body-weight of the patient Rollier and Gauvain adopt a technique in treatment by heliotherapy, by which the body is gradually exposed to the sun and sky until the whole surface area of skin is irradiated. At the Light Institute at Copenhagen and at many other places the whole body is exposed to the source of light according to a routine schedule No importance is attached to the biological response of the skin after radiation The exposure to light is systematically carried out until patients are exposed for two hours By the technique which has been described, during the whole course of treatment exposure to the source of light is controlled by the erythema reaction of the skin The object of each treatment is to produce a minimal erythema over an area of skin considerably less than one-quarter of the surface area of the body A great advantage of this technique is that the length of time of exposure is considerably shortened Any type of lamp which readily emits erythema-producing rays is suitable. With the M V L and arc lamps which were employed in these observations treatment started by exposures from 2½–5 minutes (1½–2 I K), and even after 30–40 treatments an erythema could be easily obtained by exposure of an area of skin for 10 minutes (4–8 I.K). By resting each area of skin for 10–14 days between each exposure the skin is continually maintained in a light sensitive state

Immunity of the Skin to Light

The skin rapidly develops a mechanism of immunity to light directly after exposure to ultra-violet rays and before the onset of erythema and pigmentation L Hill has shown that when a small area of skin is irradiated so as to produce a maximal erythema, a second dose of light given over one-half of an area of skin 10 minutes after the first exposure does not further notably increase subsequent inflammation and soreness in this half of the irradiated area. Perthes found that irradiation of the erythematous skin does not result in any further reaction beyond the maximal erythema reaction When the skin is desquamating the desquamating layer absorbs the whole of the ultra-violet rays, and no penetration of ultra-violet rays occurs through this On the other hand, directly after desquamation the new skin layer is exposed and is very sensitive to irradiation Erythema can then be produced with a minimal dose of light, which again renders the skin immune to light until erythema and peeling have passed away Pigmentation lessens the sensitivity to ultra-violet rays, but, as Perthes points out, it is possible to produce erythema in the pigmented skin The dose may, however have to be increased Pigmentation protects the blood from the visible rays and by converting the radiant energy into heat excites the cutaneous nerves and provokes sweating, which in its turn protects the body from being over-heated by the absorption of radiant energy

From these observations it is apparent that immunity and protection to ultra-violet radiation is produced (1) by changes occurring in the skin directly after radiation; (2) by the desquamation of the skin; (3) later to a lesser extent by pigmentation

The skin is a very active tissue and is constantly undergoing regenerative and proliferative changes The skin responds to ultra-violet radiation only when these rays can penetrate to the layers of skin beyond the horny cells of the stratum corneum. The depth of pigmentation and the penetration of light depends upon the intensity of the wave-lengths of ultra-violet rays emitted from the source of light. When the reaction to irradiation has extended deeply into the layers of the skin, this immunity persists for a longer period of time, as a larger mass of skin and tissue cells have been irradiated.

The skin of young children differs markedly from the adult skin in its behaviour to light The child's skin does not appear to be as sensitive as the adult's to ultra-violet radiation, and the erythema reactions produced are usually less intense Although the child's skin appears to possess a natural immunity to ultra-violet rays, its absence of pigment renders it very sensitive to the heating effects produced by the penetration of visible rays

In the "Copenhagen technique" the massive exposure of large areas of skin to arc lamps renders the skin rapidly light-tolerant and immune As a result the dosage has to be increased for long periods of time The work which has been described in this paper does not support this method of treatment Although the clinical results obtained by A Reyn and his colleagues are very good, it is claimed that equally good results can be obtained by this simpler and quicker technique, which it would be interesting to try also in heliotherapy It may be necessary to somewhat increase the time of exposure towards the end of the treatment, but the careful control of dosage during the preliminary stages of treatment, and the observation of the skin reactions with each dose of light, give place to a simple systematic technique for phototherapy.

The experiments described in this paper were carried out at the National Institute for Medical Research, Hampstead, N W I wish to express my gratitude and thanks for the help given me by Dr. Leonard Hill and Captain S R Douglas while the work was progressing

SPINAL ANÆSTHESIA IN INTUSSUSCEPTION OF INFANTS.

BY HAMILTON BAILEY, F R C S ENG,
GILLSON SCHOLAR SOCIETY OF APOTHECARIES, SURGEON,
DUDLEY ROAD HOSPITAL, BIRMINGHAM

THE advantages of spinal anæsthesia in acute intestinal obstruction are now widely appreciated, for it is recognised that one of the greatest contra-indications in all modern emergency surgery is an anæsthetic via the respiratory passages to a patient in the throes of fæcal vomiting Again, the picture of an unhappy surgeon engaged in a sisyphean task of approximating the peritoneum over a sea of distended and unruly intestinal coils has, by virtue of intrathecal anæsthesia, passed, and given place to quiet and orderly suture of the abdominal wall Whatever objections may be raised against intrathecal anæsthesia, few will deny that it has at least played a part in improving the results of the treatment of acute intestinal obstruction

The object of this paper is to set forth some advantages of extending spinal anæsthesia to intestinal obstruction during infancy, and is based upon observations made upon a short series of cases of intussusception so treated

Technique and Dosage

Stovaine in saline (May and Baker) was used in all cases A word of warning is here necessary It is essential that it be stovaine *in saline*, for should the older preparation, stovaine in glucose (which is still used by some operators), be injected, disastrous results would most certainly follow the instructions outlined here So great is the danger, in emergency, of confounding the phials of these two preparations of stovaine—whose application in theory and practice involve entirely dissimilar principles—that it should be compulsory for all manufacturers to issue stovaine in saline in a capsule of a conventional colour

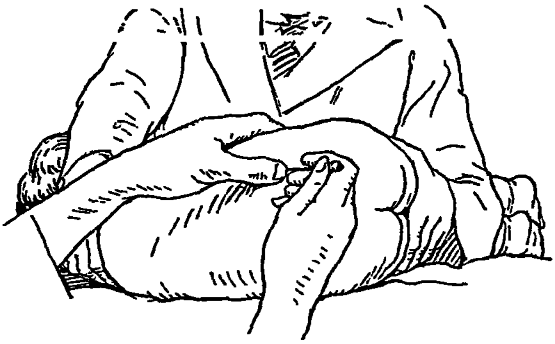
Dosage—0 2 c cm of stovaine in saline was the standard dose used, but this must vary with the weight of the baby

The lateral position of the patient is adopted for spinal puncture, this position is maintained by an assistant on the left-hand side of the table By passing one arm round the baby's neck, and the other under its knees, the assistant can steady the patient and maintain flexion of the vertebral column (Fig 1) The operator will find it convenient to be seated Barker's needles, so generally used for spinal puncture, are much too large, and are quite unsuitable for infants A smaller needle should be substituted The needle is introduced between the second and third lumbar vertebræ

Observations lead one to believe that in these cases the reduction of intracranial pressure consequent upon the removal of cerebro-spinal fluid increases shock considerably The cerebro-spinal fluid should therefore not be allowed to escape There is no need to mix the stovaine intimately with the cerebro-spinal fluid by repeatedly withdrawing and inserting the piston of the syringe I have reason to believe that this is a dangerous practice, and sometimes disseminates the anæsthetic to the higher segments of the cord

The anæsthetic having been introduced, the puncture wound is sealed by collodion in the usual way ½ c cm of pituitrin is injected subcutaneously to counteract a fall in blood pressure, and the operating table may be tilted by the head 20° with the same object in view I usually ask the nurse to place the corner of a piece of gauze soaked in glycerol in the patient's mouth, and as often as not the child sucks the gauze quite happily during the operation.

FIG 1



Position for spinal puncture

Advantages

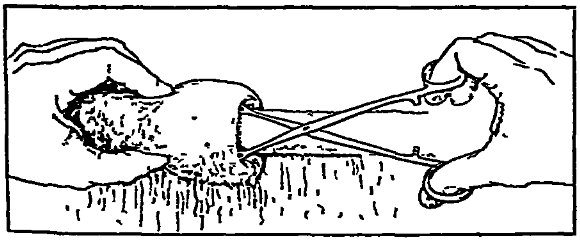
The stovaine effectually blocks the painful impulses passing from the intestines to the spino-thalamic tract, and frequently, a few moments after the injection, a child howling with pain becomes quite peaceful

The aphorism of Jacobson that the prognosis in intussusception varies inversely with the time that the infant is on the operating table applies to reduction under general anæsthesia Within reasonable limits, when spinal anæsthesia is being used, there is no particular necessity for speed Refinements of technique, such as clipping towels to the cut edge of the skin and displacing the rectus laterally (instead of splitting that muscle) are permissible in the majority of cases Owing to the absolute muscular relaxation, the mass which constitutes the intussusception can usually be delivered through the wound into hot, saline-soaked gauze This is always possible as soon as the splenic flexure has been passed Extra-abdominal reduction, combined in stubborn cases with Daw's method of stretching the intus suscipiens (Fig 2), has considerably minimised the necessity for resection and its concomitant risks

Under general anæsthesia, and especially when gas and oxygen are being used, there is at least some difficulty in closing the abdominal wall in layers Not infrequently the difficulty is insurmountable, and the only possible means of dealing rapidly and efficiently with the situation is to have recourse to through-and-through interrupted suture Whilst the results of this somewhat crude but effective method of closing the abdomen are astonishingly good, it must be admitted that complications occasionally directly result from its use For instance, "burst abdomen" is a well-known complication after reduction of intussusception under general anæsthesia. So far it has not occurred after spinal anæsthesia, and it is highly improbable that it will.

Again, when the peritoneum is not accurately approximated, coils of intestine are very likely to become adherent to the wound. A case of acute on chronic intestinal obstruction in a child of 3 was recently seen at necropsy. The cause of the obstruction was found to be adherent coils of ileum to a laparotomy scar. An intussusception had been reduced two years previously. Lastly, it is obvious that an abdominal wall closed hastily and with difficulty is more likely to predispose to a ventral hernia than one which has been accurately sewn in layers.

Fig. 2



Daw's method of stretching the intussuscipiens.

It will be noticed that there was one death in this series. The child had been ill 68 hours before it was submitted to operation. Nevertheless, though very shocked, it was not more collapsed than several others of the series. As the operation was about to commence the child stopped breathing. The heart continued to beat for some seven minutes after the cessation of respiration; but in spite of every effort at resuscitation for half an hour death occurred. The necropsy revealed a small gangrenous ileocolic intussusception. I believe this death was due to stovaine poisoning. On reconsidering the case, I remembered that the syringe which was being used was indistinctly marked. Further, seven hours before this operation I had pricked my finger in the course of a laparotomy upon a patient with a virulent streptococcal peritonitis, and a long illness had already commenced. It seems probable that an overdose of stovaine was given and it behoves one to make quite certain that the syringe which is being used is marked very clearly in tenths of a cubic centimetre.

In spite of this failure I have every confidence in the method. The greatest advantage that spinal anæsthesia has to offer is an absolutely relaxed abdomen, which facilitates the work of the surgeon, and prevents many insults to the plexuses of Auerbach and Meissner.

After-treatment.—The patient is returned to bed and anti-shock treatment continued. The foot of the bed is raised, and continuous rectal saline administered by means of a Souttar's apparatus. Nepenthe, ♏ 1, is given by mouth every three hours.

Clinical and Laboratory Notes.

A CASE OF

SIX FACETED CALCULI FOUND IN THE SUBSTANCE OF THE SUBMAXILLARY GLAND.

By W. Ingledew Daggett, M.B. Camb., M.R.C.S.,
HOUSE SURGEON, KING'S COLLEGE HOSPITAL.

Calculi in Wharton's duct and in the substance of the submaxillary gland are not uncommon; the following case, however, presents unique features:—

An adult male, aged 36, recently attended at the hospital complaining of a large swelling on the left side of the neck immediately below the lower jaw. The swelling had first been noticed about 18 years previously, when no larger than a marble. No inconvenience had been caused, and there had never been any pain or increase in size during meal times. Five years ago the patient had a bad cold, and a marked increase in the swelling became evident, with associated pain and throbbing until a sudden and offensive discharge into the mouth relieved the condition, decrease in size following almost immediately. Several similar attacks occurred during the last five years, all associated in onset with a cold in the head, and relieved by an offensive intrabuccal discharge. On each occasion the swelling had subsequently decreased in size, yet each exacerbation had left it larger than formerly. The patient was often conscious of something hard pressing upon and limiting the movements of the left side of his tongue; several times, when pressing upon the swelling, he had felt a distinct click which he described as "something hard hitting against the lower jaw."

When this patient first presented himself for examination he was in what he termed "one of his attacks." He looked ill and his temperature was 100.2° F. There was a swelling the size of a hen's egg in the left submaxillary triangle; this was exquisitely tender on palpation; the overlying skin was red, hot, and attached to the mass. Oral examination demonstrated that the orifice of Wharton's duct was red and prominent, pus could be expressed by gentle pressure. With one finger in the mouth and the other hand just below the horizontal ramus of the mandible, a marked degree of fixity was noted; despite the limited lateral mobility, pressure outwards imparted to the examining fingers the uncanny "click" alluded to by the patient.

The diagnosis of calculus in the submaxillary gland was easy; the presence of pus flowing into the mouth pointed to secondary infection, whilst the size and fixity of the gland were certainly due to previous attacks of inflammation, which had caused fibrous thickening of the gland stroma and adhesions to surrounding structures. The fact that pain and increase in size associated with taking food had not been noticed showed that the duct had never been obstructed; this was confirmed by the easy passage of a fine probe along the duct.

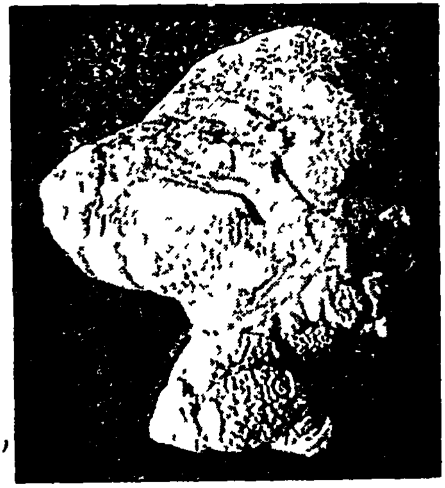
From an X ray photograph the deduction was made that a single large branched calculus was present in the substance of the submaxillary gland. The obvious procedure was to remove the whole gland from the outside, owing to the size of the swelling and periglandular fibrosis, and the patient was admitted to the ward. The teeth were very septic and received attention. Frequent mouth washes of chloramine-T ½ per cent. were used until the inflammation had subsided.

Operation.—Access to the gland was effected through a curved incision, with its convexity downwards, extending from a point just behind the symphysis to the angle of the mandible. The gland was dissected out piecemeal, the firm adhesions causing great difficulty. The facial artery was cut and secured, whilst subsequent weakness of the left side of the mouth showed that the buccal branch of the facial nerve had been damaged. A corrugated rubber drain was inserted and the wound closed. On opening the gland no less than six separate calculi were found, all faceted and fitting into one another so closely that the appearance of a single calculus in the X ray photograph was not surprising. The accompanying photograph shows the branched appearance and rough nodular surface of the composite mass; the separate calculi have been fitted together by plasticine in order to show their disposition before separation. The total weight was 16 g., the largest of the six weighed 6.5 g.

Discussion.

The question as to how the facets arose is interesting. It is possible that the calculi were formed separately in a pre-existing cystic space in the gland,

and that mutual pressure, as in the case of gall-stones, was in part responsible for the condition Retention cysts in the submaxillary gland have been described, but they are not common Assuming the presence of such a cyst, some low-grade infection would give rise to retention of minute plugs of mucus, desquamated epithelium, and bacteria, around which phosphates and carbonates of lime would be deposited The stones would become larger until they filled the cyst, further deposit of salts would then only be possible on the surfaces not actually in contact with one another, and so faceting would result Pericystic deposition of fibrous tissue, due to irritation, would explain the fixity of the calculi in the gland substance.



The composite mass of six faceted calculi fitted together with plasticine as they lay in Wharton's duct × 2

In my opinion the condition did not arise in this way, but the several component parts were formed in separate but adjacent parts of the gland, such a condition has been described before, but radical treatment has been instituted before facets have had time to form In the case in question, I assume the presence of six separate calculi close together but separated from each other by a small amount of glandular tissue; as growth continued this intervening glandular tissue, through compression, would atrophy and finally disappear When this stage had been reached only time was necessary for the development of facets, for lime salts could only be deposited on the free surface of the composite mass The fact that between the smallest calculus and the one into which it fitted I found a process of fibrosed glandular tissue continuous with that surrounding the main mass is in support of this view It is very rare for such a condition to be allowed 18 years in which to develop

In conclusion, I wish to express my gratitude to Mr. Cecil P G. Wakeley for allowing me to operate upon and publish this case

A CASE OF

SIMULTANEOUS ABDOMINAL AND TUBAL PREGNANCY

By M Sourasky, M D Leeds, F R C S Edin ,
SURGICAL REGISTRAR, LONDON JEWISH HOSPITAL

Cases of twin ectopic pregnancies are sufficiently rare to be worth recording

Mrs I L , aged 32, was admitted to the Mansfield Hospital, Nottingham, on Nov 23rd, 1021, suffering from abdominal pain, vomiting, and a large abdominal tumour I did not see the patient at the time, but I understand it was diagnosed ? hydatidiform mole She remained in the hospital for five weeks, and as all her symptoms abated she was discharged and lost sight of

On March 8th, 1024, after a period of over two years, she was readmitted with exactly the same swelling, pain, and fæculent vomiting She stated that she had been in fairly good health since leaving the hospital except for rather severe constipation and occasional attacks of vomiting and abdominal pain Menstruation was irregular and scanty

Condition on Examination —On abdominal examination a large mid-line swelling from xiphisternum to pelvis was found It was smooth and slightly movable from side to side, but not vertically The umbilicus was everted The whole abdomen was tender, rigid, and distended, so that on palpation one could make out nothing beyond a large tumour Vaginal examination revealed nothing except a slightly patent os The breasts were prominent and no colostrum could be expressed

Her general condition was alarming The temperature rose to 103–104° F , the pulse was rapid and thready, and the vomiting frequent and fæculent It was evident that the case was one of general peritonitis superimposed upon an abdominal tumour of nearly three years' standing, the nature of which was not known

Mr A. Hunnard, under whose care the patient was readmitted, and to whom I am indebted for permission to publish this case, asked me to operate on her

Operation —Under general anæsthesia in the lithotomy position I found the uterus enlarged to about 5 in , the os patent, admitting with great ease Hegar's dilators, and the uterine cavity empty I therefore decided to perform laparotomy, at which Mr A R Tweedie kindly assisted me

On opening the abdomen a large sac, through which a fœtus was palpated, was seen. This sac was intimately adherent to the abdominal viscera, and on tracing it downwards we found it originating at the right pole of the fundus of the uterus, the base of its attachment measuring 1 in. by ½ in There was also a pendulous mass hanging from the right side of the uterus at the site of the right Fallopian tube and ovary The left tube and ovary were normal The uterus was enlarged, and, with the exception of the sac originating at its right upper pole, and the pendulous mass at the right side, looked quite normal The peritoneal cavity was filled with a serous exudate and multiple friable adhesions

In view of the patient's serious condition, and the multiple dense attachments to the various viscera, the removal of the sac en masse was considered inadvisable Hence an incision into the sac was made and a slightly macerated fœtus of about eight months was extracted The placenta and the inner surface of the sac were gangrenous, and the sac was full of dark, highly offensive fluid After removing the gangrenous tissue and carefully mopping out the purulent fluid, we closed the abdomen, draining the sac and the peritoneal cavity Though the wound drained well, and though all measures to improve her general condition were undertaken, the patient died five days after the operation

Post-mortem Examination —No communication was found between the sac and the uterus It was impossible to detach the sac from the viscera The pendulous mass on the right side of the uterus contained another fœtus of over three months, as the sex could be determined The uterus, the sac, and its attached viscera were carefully removed for microscopic examination and museum purposes Unfortunately the specimen was destroyed

Commentary

One is faced with the problem as to how the abdominal pregnancy originated There are three possibilities 1 It began as a twin pregnancy in the right Fallopian tube, one ovum gaining entry into the peritoneal cavity and eventually becoming attached to the right upper pole of the uterus, either by being extruded through the abdominal ostium or by rupturing through the wall of the tube 2 It began as a primary abdominal and a tubal pregnancy 3 It began with one pregnancy in a rudimentary horn of a uterus unicornis, and another in the right Fallopian tube

The first hypothesis is not feasible, because the patient's history is too colourless to suggest a ruptured tubal gestation or an extrusion of a fœtus through the abdominal end of the Fallopian tube The second hypothesis is possible but highly improbable. One could hardly conceive an abdominal pregnancy attaching itself to the upper pole of the uterus by a narrow peduncle, as was found in this case; and some authorities deny the existence of primary abdominal pregnancy per se Therefore I am inclined to think that the pregnancy began in a rudimentary horn, which lost its communication with the uterine cavity during the three years of the fœtus's existence

It is difficult to come to a definite conclusion as to when the tubal pregnancy started—whether it was a case of superfœtation or simultaneous ectopic pregnancies Apparently, when the patient was admitted the first time, she had gone to full term, and a spurious labour had occurred with severe abdominal pain and vomiting. The fœtus must have died during that process.

Summary.

The interest in this case lies in the following facts

1 The woman lived fairly comfortably for nearly two and a half years with two dead fœtuses in her abdomen (*a*) One about eight months old lying in a special sac which was tightly adherent to the viscera, and apparently originating from the upper pole of the uterus from a rudimentary horn ; (*b*) the other in the right Fallopian tube over three months old, which had been there for an undetermined time

2 The placenta of the large fœtus was gangrenous, and the fœtus itself was just beginning to undergo decomposition

3 A rare combination of abdominal and tubal pregnancies

MENTAL DISEASE AND DEFICIENCY

WORK OF THE BOARD OF CONTROL IN 1925

THE twelfth annual report [1] of the Board of Control, on which we made some general comment last week, records that there were 133,883 certified persons under care at the beginning of 1926 This was an increase of over 2000 on the previous year, but the Commissioners consider that it is parallel with the increase in population and does not afford evidence of any increase in the incidence of insanity The sex percentage among the private patients was 34 8 males and 65 2 females, but if service and ex-service patients are included the relative figures are altered to 59 and 41 Among rate-aided patients the sex distribution showed a slightly higher figure for males 41 7 per cent, or 44 3 per cent when the service cases are included The recovery-rate for the whole country, calculated as usual on the direct admissions, was 31 8 per cent, and the death-rate 7 6 per cent.—the lowest ever recorded.

Accommodation

The question of available accommodation is rapidly becoming serious, and the Board called a conference in April, 1925, to consider it Methods of relieving pressure that were recommended include · (1) Arrangements with boards of guardians to transfer harmless senile patients to Poor-law institutions, (2) extended use of boarding-out, discharge to relatives, and discharge on trial of all suitable patients, (3) building on to existing mental hospitals separate admission and convalescent villas and homes for the nurses As circumstances may differ in different areas, the Board is collecting information with a view to calling regional conferences Regions have been mapped out in such a way that each group of mental hospitals is collected around a teaching centre, and it is hoped that the scientific progress of psychiatry may be furthered by contact between the institutions and the universities

Scientific Equipment

The report states that "every public mental hospital should possess a laboratory" and urges every institution to appoint a properly trained pathological officer and laboratory assistant without delay Possibly the grouping of the hospitals around the universities may further the encouragement and coordination of research by the appointment of one of the university pathologists as visiting pathologist to the mental hospitals in his area The Commissioners urge the speedy installation of an X ray apparatus and the appointment of a visiting radiologist; it is particularly important when dealing with mental patients to be able to locate fractures and foreign bodies precisely, and also to be able to apply X ray treatment clinically where indicated While it cannot yet be stated with any assurance that ultra-violet radiation has any specific action on psychotic states, five county and one registered hospital have installed the apparatus for the treatment of such conditions as malnutrition, autotoxæmia, and tuberculosis The Commissioners feel that patients cannot be adequately treated without a clinical room attached to each ward where they can speak privately with the medical officer and where he can carry out the simple everyday tests of clinical medicine A complaint of increasing frequency is the lack of opportunity the patients have for talking with the medical officer, and although this is no doubt partly due to the very large numbers accommodated in some of the institutions, yet the Commissioners feel that the difficulty might be largely met by the routine use of these clinical rooms

Amenities of Life

In conformity with their general policy of treating inmates of mental hospitals as nearly as possible like those of other hospitals, the Board urge the greatest possible freedom in correspondence and visits, and have issued a circular in which they ask all superintendents to see that the patients are fully informed of their rights in the matter of visits, letters, and parcels

The scheme of dietary drawn up by the Board has been followed in most of the hospitals, and there is no doubt that the food supplied has, on the whole, improved very markedly in recent years Rigid weekly scales have been abolished, and kitchen equipment has been improved The provision of a really good diet necessitates capital outlay on the equipment, but economy is effected in the end The average weekly cost of maintenance was 23*s*

Infectious Disease

Three institutions had outbreaks of mild small-pox, but there were no deaths, and the energetic action of the medical staffs quickly confined the epidemics within narrow limits Influenza seems to have been more prevalent in 1925 than in 1924, but of a milder type The problem of intestinal disease in mental hospitals was dealt with in a recent issue of THE LANCET (August 21st, pp 377–391) While the measures taken to prevent and combat these conditions are very much more efficient than they used to be, the report urges on all institutions the great importance of making their water- and milk-supply, sewage disposal, and laundry work above reproach It is also suggested that the flushing system in w c.'s should be worked by a floor pedal to avoid contact with hands that may be contaminated Typhoid and para-typhoid continue to show a slow but disquieting annual increase 147 cases being notified during 1925 Curiously, nearly 80 per cent. of these cases are in women, whereas in the population outside male cases predominate Early diagnosis and organised search for carriers ought to combat these diseases successfully Dysentery has shown a steady decrease in incidence, while tuberculosis has remained at the low figure it reached last year, less than 12 per 1000 The distribution of the last-named disease suggests to the Commissioners that there are still some unrecognised predisposing factors in certain hospitals. The figures of mortality from phthisis show a very gratifying improvement from 17 per cent of all deaths in mental hospitals in 1909–14, to 11 4 per cent. in 1925 The improvement in dietary is probably the chief responsible factor, others being open-air nursing, better ventilation, and vacuum cleaning

---

[1] H.M. Stationery Office 12*s* 6*d*

Staffs and Out-patient Treatment.

Some half dozen superintendents resigned during the year, and it is interesting to note that the first appointment of a woman superintendent was made in the summer of 1925, when Dr. Jean Shortt was placed in charge of The Lawn, Lincoln The problem of mental nurses was made the subject of a special conference in April, 1925, and the Board subsequently issued a circular setting out their suggestions on what should be done to ensure a good service The circular presses for uniform action throughout the country to attract the best type of nurse by providing adequate remuneration, suitable quarters, and club rooms Those superintendents who have tried the experiment of using women nurses for male patients are practically unanimous in its favour

The report devotes a special section to the importance of providing out-patient treatment in connexion with mental hospitals, and particularly emphasises the value of cooperation with general hospitals A score of hospitals throughout the country now have out-patient clinics, where patients are seen by a member of the staff of a mental hospital; but very much remains still to be done, and the necessity of providing beds and social workers for these clinics is not yet adequately appreciated

General Paralysis and Encephalitis Lethargica.

Induced malaria was used at 42 institutions on some 444 general paralytics in 1925 13 7 per cent of these have been sent home greatly improved and no harm has resulted from the treatment The Board admits the point of view of those who maintain that the apparent recoveries should be classed with the remissions which so often occur without treatment, but feels that the figures are too striking to be deprecated and continues to encourage this therapeutic experiment There are now in mental institutions about 320 patients suffering from the after-effects of encephalitis lethargica These young people need occupational training and facilities for special grouping, and the Board is glad to record that the local authorities for London and Lancashire have collected their cases together and that 30 beds have been specially put aside at West Park, Epsom, for research and treatment; 25 beds have also been set aside at Winchmore Hill, and the results of patient work there have been gratifying

Research Work in Mental Hospitals

The report includes, as usual, abstracts of the research carried out in the various mental hospitals The amount of research done, in addition to routine pathological work, is steadily increasing This year's reports record a number of interesting and valuable pieces of work on many subjects, including intestinal infections, malarial treatment of general paralysis, basal metabolism, biochemistry of the blood, reaction of the cerebro-spinal fluid, pellagra, laboratory aids to diagnosis, and ultra-violet light and radiant heat in treatment

Mental Deficiency

A large section of the report is taken up with the very serious problem of the mental defectives As we pointed out in our comment on last year's report (THE LANCET, 1925, ii , p 655), the lack of accommodation is acute, and the last 12 months have seen no improvement " The failure of local authorities," says the report, " to fulfil their duties is hampering the beneficent objects of the Mental Deficiency Act Every day brings to our notice urgent and often most pitiable cases for whom no accommodation can be found Mere figures can never reveal the urgent need for continuous care for defectives There are human aspects of this social evil which cannot be found in statistics " Three typical cases are given in full as illustration of the lamentable state of affairs

Discussing the marriage and procreation of defectives, the report weighs the methods of sterilisation and segregation, and in view of the terrible results, both social and personal, of the present free propagation of deficients, suggests that the two measures might profitably be worked together Sterilisation alone will certainly not solve the problem, nor affect the immediate need for institutional accommodation, but since this is so grossly inadequate it might, the Board feels, be both humane and expedient to try sterilisation followed by return to some form of community life on licence.

While ascertainment is undoubtedly improving, a large number of defectives have not yet been found The reports of local authorities make it clear that a specially trained officer should be appointed or else that the local voluntary association should be used A circular has been sent to local authorities and 115 out of 124 have replied , the report gives a summary of their answers Twenty-one occupation centres are now at work and producing good results, in spite of the lack of proper facilities in many places An increasing number of boards of guardians are employing skilled occupational trainers The appointment of special medical officers is proceeding slowly and the Board doubts whether the Act will be properly worked until each district has such an officer, with special knowledge and experience, whose principal work is mental deficiency There is considerable difficulty in obtaining doctors with adequate training; only 108 out of the 333 so far appointed have had any special experience On Jan 1st there were 21,082 defectives under care and 55,480 " ascertained " The death-rate among those in institutions was 2 per cent. ; 31 per cent. of these being due to tuberculosis, 20 per cent to pneumonia, and 11 per cent to epilepsy.

MENTAL HOSPITAL REPORTS

PRIVATE HOSPITALS

Barnwood House Hospital, Gloucester, has 142 patients, 14 of whom are on a voluntary basis There was a good deal of influenza in the spring but no other illness , the death-rate was 9 15 per cent The recovery-rate was 48 per cent , and the Visiting Commissioners note with satisfaction the amount of individual and intensive treatment The staff of visiting specialists is increasing; the hospital now has a consultant physician, surgeon, and pathologist, and a dentist is to be appointed One general paralytic treated by induced malaria was discharged recovered and is keeping well The patients had the advantage of a seaside house at Weston-super-Mare for the summer and many of them have full parole Verandahs and a dental room were added during the year and new arrangements at the cowsheds have resulted in a milk-supply of high purity Forty-one per cent of the nursing staff hold their M P.A. certificate

The Retreat at York publishes a report illustrated with delightful pencil drawings of the estate There were 206 patients in residence at the beginning of 1926 The number of admissions during 1925 reached a record figure and over 56 per cent of them were voluntary The death-rate was 7 per cent , and the recovery-rate 28 per cent The hospital was free from epidemic disease Malarial treatment of general paralysis has been continued with varying but on the whole encouraging results, and the use of gland extracts is being pursued Many of the patients had the benefit of a " summer holiday " in the house rented at Cloughton The male side has been satisfactorily reorganised and the Gentlemen's Admission Hospital is described as " a model of what such a department should be " A new nurses' home is practically complete Fifteen patients have full parole and 48 more walk out attended Twelve nurses obtained the M P A. certificate during the year and a number more passed the preliminary examination A most important development is the inauguration of a clinic at the County Hospital for mental out-patients, which is to be run with the cooperation of the five mental hospitals in the district

A PAMPHLET ON VENEREAL DISEASES

A REPRINT of the chapter on Venereal Diseases from the annual report for 1925 of the Scottish Board of Health has been issued for separate circulation. The pamphlet[1] is intended to impress on the public the importance of early and sustained treatment of venereal disease, also to enable the practitioner to realise the extent to which the public health depends on the thoroughness of his methods of diagnosis and treatment, and to indicate when he ought, in the interest of his patient, to have recourse to the public services provided. We have already[2] drawn attention to this section of the report as a summary of the pathology, sociology, symptoms, and successful modern treatment of these diseases, which is more informative than many large text-books on the subject. In a covering letter the Scottish Board of Health suggest that local authorities should purchase copies of the pamphlet and supply them to their members and officers, and also to all practitioners working in their areas. In the introduction the pamphlet is said to be "a descriptive summary of the methods employed" which "represents the actual practice" of the 45 centres now established in Scotland. Those who are led to expect an account of the actual methods employed at the Scottish centres in diagnosis and treatment—if, indeed, they all adopt the same routine—and to find material for comparison with methods adopted in England will be disappointed. While details are omitted, very properly in a pamphlet designed for lay as well as medical readers, enough information is given to indicate that the practice does not differ essentially from that adopted elsewhere in the United Kingdom.

Syphilis

Of the 16 paragraphs, filling six pages, devoted to syphilis, the first is concerned with a historical account of the discoveries of the last 20 years; the second to an estimate of the wide diffusion and manifestation of the disease. The third brings to notice the extreme viability of the spirochæte; transmission of infection, manifestations, innocent infection, other modes of acquiring syphilis, the initial lesion, and subsequent stages of syphilis are then discussed in turn. Paragraphs follow on the curability of the disease and on the importance of early and persistent treatment which must be "commenced with promptitude, pushed with vigour, and continued for long." This section is completed by brief notes on the use of mercury, bismuth, and other drugs, neosalvarsan, treatment and infectivity, standard of cure, early diagnosis, and the interpretation of the Wassermann test. The standard of cure accepted is a persistently negative Wassermann reaction in the blood over a period of two years.

Gonorrhœa.

To gonorrhœa is allotted a little more space, well divided into 22 paragraphs. Diffusion and ravages, the organism of gonorrhœa, mode of transmission, manifestations, and general course are first described. A list of complications and sequelæ follows, also warnings as to the dangers of a definite prognosis. The general principles of treatment at all stages are next dealt with. It is stated categorically that chronic gonorrhœa in the male cannot be effectively treated without the routine use of the urethroscope and the advantages of irrigation by means of a can and nozzle over urethral injections with a syringe are emphasised. The standard of cure adopted is as follows:—

Standard of Cure in Gonorrhœa.—A patient who has had gonorrhœa should not be regarded as cured (nor should one who believes that he may have contracted gonorrhœa be assured that he has not) until—

(a) there is either no discharge from the urethra or only an occasional clear mucoid drop which on repeated examination is found to be devoid of gonococci;

(b) the urine shows an absence of pus or gonococci, the latter on repeated examination if threads be present;

(c) the prostate is healthy—that is to say, there is absence of pus and of gonococci on repeated examination of the expressed secretion;

(d) examination by the urethroscope shows no indication of lesion; or, alternatively, no lesions are palpable by means of an exploratory bougie;

(e) the administration of provocative vaccines gives a negative result—namely, no exacerbation (however slight) of symptoms;

(f) complement-fixation test gives a negative result. (Always bearing in mind that a previous administration of vaccine will produce a positive result.)

No standard of cure is suggested for gonorrhœa in women, and this in itself is a sign of the chronic and intractable nature of the disease when it affects the female genital tract. As to its treatment, careful preliminary swabbing, irrigation of the urethra, douching and swabbing of the vagina, local applications to the cervical canal and special treatment, by cautery, incision, or otherwise, of infected glands and their orifices—any or all of these may be necessary.

Notes on rheumatism and ophthalmia, on gonorrhœa in children, and on untreated cases conclude this section. Brief accounts of soft chancres and of balanitis and warts are included in the pamphlet, where a list of V.D. centres in Scotland and certain local statistics also find a place. We quote in full a paragraph which is more controversial than most, entitled

The Treatment of Venereal Disease by the General Practitioner.

During the last 20 years the diagnosis and treatment of syphilis and gonorrhœa have made such rapid progress and have indeed been so radically altered that it has been hard, if not impossible, for the general practitioner to keep abreast of the most recent knowledge and the most approved procedure. To a certain extent the specialist in his consulting-room or in the venereal diseases clinic, of which 45 have now been established in Scotland, has been able to meet the difficulty and supply the lack; but it is certain that he has not been able to reach more than a substantial proportion of all those affected. Adequate treatment will only be meted out to those suffering from venereal disease—whether man, woman, or child, whether infected by contact or congenitally, innocently, or otherwise—when the *general practitioner* is in a position to supply that need. That will come about gradually. Indeed, it has already commenced, and will become more general as graduates pass out from the medical schools after a training in which clinical study of the venereal diseases is an essential part. At present, in the transition stage, it is important for each general practitioner to know what is feasible for him and what not. Guided, if need be but not necessarily, by the specialist, he can supply the whole treatment of syphilis, provided only that he has sufficient skill for intravenous injection or, alternatively, uses one of the drugs prepared for intramuscular use, and that he has access to a laboratory for the performance of the Wassermann test. With regard to gonorrhœa it is different. The acquisition of skill in the use of the urethroscope, of bougie, sound, and dilator, and in the examination of the prostate, is at least in most cases beyond the reach of the busy general practitioner. In the case of gonorrhœa in the female the treatment is, or at least may be, so intricate and so protracted that it is practically a matter for the specialist alone. Even in the case of syphilis the ideal is for the patient's medical adviser to be guided, and if need be aided by a specialist from time to time.

Practitioners may not agree with all the statements in the paragraph quoted. The idea that they may properly undertake the treatment of syphilis, whereas that of chronic gonorrhœa in men or women should be left to the specialist, is the reverse of what would have been recommended ten years ago, but it is a point of view that has much in its favour. We quoted last week (p. 618) a list of services which, in the opinion of certain local medical and insurance committees in England and Wales, could properly be undertaken by a general practitioner of ordinary professional competence and skill. "The treatment of gonorrhœa by irrigation and medicine" was included among these, whereas "removal by dissection of Bartholin's gland" and "intravenous administration of novarsenobillon" were among those considered to belong to another category. This and other suggestions in the pamphlet make it worthy of study by the practitioner as well as by the members of the lay public for whom it has been in part compiled.

Reviews and Notices of Books.

ALLERGIC DISEASES

Allergic Diseases Diagnosis and Treatment of Bronchial Asthma, Hay-fever, and other Allergic Diseases By W STORM VAN LEEUWEN, M D, Director of the Pharmaco-Therapeutic Institute, Leiden, Holland London J. B Lippincott Company 1926. Pp 142 18s

THOSE who have read Dr Van Leeuwen's papers will be glad to have an account of his researches and present views in book form To others who are not acquainted with his work this book can be recommended as presenting probably the soundest and most up-to-date account in this language of allergic diseases and of asthma in particular Attention may be directed particularly to his account of the alteration of purin metabolism in asthmatics and to his discussion as to whether allergy, or hypersensitiveness to foreign substances as it is more commonly called in this country, is or is not an anaphylactic phenomenon In previous papers Dr Van Leeuwen has followed Coca in arguing that there is very little connexion between the two subjects, but as the result of a careful review of recent work he now inclines to the belief that anaphylaxis may explain most cases of hypersensitiveness, although those cases of asthma which have followed immediately on a first contact of a child with a specific allergen cannot be due to this cause He describes the importance of skin tests, and in particular of his human dandruff test, as a means of diagnosing the condition of allergy in a patient rather than of indicating what is the specific cause of the patient's attacks His theory of allergic diseases is that in the first place the allergen—not necessarily a protein, in some cases a drug—must gain entrance to the blood either through the skin or mucous membrane This implies increased permeability, since ordinarily the organism does not allow such poisonous substances to enter This increased permeability may be due to diseases of the skin or mucous membranes, such as eczema, coryza, bronchitis, &c, or it may be due to the fact that the allergen is combined with an irritating substance that injures the epithelium and allows it to enter. When the protein substance has obtained entrance to the blood stream immunity may be gained, or, if continued doses of the allergic substance are received, anaphylaxis may result

The treatment of asthma is admirably discussed Dr Van Leeuwen believes that the majority of cases are due to substances in the atmosphere, or miasms as he calls them, which may be present in one locality and not in another, he has treated one case by keeping the patient in a miasm-proof chamber by filtering the air admitted He has had successful results in other cases, and claims that the method has been modified so that it is not unreasonably expensive Further details as to the procedure would have been welcome

Asthma Its Radical Treatment Second edition By JAMES ADAM, M A, M D, C M, F R F P S Glasg, Hon Surgeon, Diseases of the Ear, Nose and Throat, Glasgow Royal Infirmary London Henry Kimpton 1926 Pp 224 12s 6d

IN our present state of knowledge of the pathology of asthma its treatment is bound to be largely empirical, and it is the various suggestions of the author on the subject of treatment, and in particular his elaborate dietary given in the first appendix, that are the most valuable parts of the book. For the rest, the author originally started out, as is clear from the introductory chapter, from the thesis that asthma is primarily a toxæmia which occurs partly in the bowel and partly in the tissues from the absorption of nitrogenous poisons or from an error in nitrogenous metabolism, the result of imperfect oxidation This was evidently his view at the time of the first edition of the book, and he seems reluctant to depart from it, though it is clear from later chapters that he now admits the importance of allergy, at any rate in some cases

There is something very baffling in the subject of asthma, for the views expressed not only as to its ætiology but as to its treatment, differ so widely For instance, Mr Adam states that nasal polypi are often present in asthma, and that it is in such cases that nasal operations are most hopeful, whereas another well-known writer maintains that the removal of polypi in certain cases makes the asthma worse The clinical part of the book is well written, but when the author discusses theory he often becomes too hypothetical, as when he suggests that the large number of eosinophil cells are present in asthma in order to absorb acid, and so preserve the alkalinity of the blood It is a pity that he has not given a fuller account of his figures for the analysis of blood and urine, as averages are apt not to be very convincing to the critical reader, and the same is true when the latter reads about the results of analysis in "typical" normal and "typical" asthmatic subjects Such data could quite well be put in extenso in an appendix without burdening the text with too much detail

The book is written almost entirely from one point of view Non-specific therapy is mentioned, but there are no directions as to how it can be carried out.

Hay-fever and Asthma By RAY M BALZEAT, A M, M D, Instructor in Medicine, University of Oklahoma Medical School, Consulting Physician to St Anthony Hospital Philadelphia F A Davis Company. 1926 Pp 198 $2

THIS book is said in its sub-title to be "a practical handbook for hay-fever and asthma patients" It contains a vast amount of information of a popular type concerning the various proteins to which such patients may be sensitive, but though the author mentions the known facts concerning the inborn tendencies of these diseases, he fails to bring out the importance in treatment He does not convince us that the intensive education of such nervous persons in the possible causation of their symptoms may not be mischievous rather than helpful

PROTOZOOLOGY

By C M WENYON, C M G, C B E, M B, B S, B Sc Lond, Director-in-Chief of the Wellcome Bureau of Scientific Research, formerly Protozoologist to the London School of Tropical Medicine. London Baillière, Tindall and Cox 1926 In two volumes Pp 1563 84s.

THE science of protozoology, on the scale exemplified in this work, is of comparatively recent growth The impetus to its development was given by the historic researches of the pioneers in tropical medicine a quarter of a century ago, but systematic study of these lowly organisms has been a matter of gradual evolution and has sadly lagged behind the sister subject of bacteriology Even at the present day protozoology, owing possibly to the absence of a reliable comprehensive treatise, is little but a name to many medical graduates, so that the appearance of Wenyon's work is timely It is an authoritative survey by one who has devoted much of his life to the study of this rapidly expanding science and sees it in admirable perspective We are not surprised to learn that more than six years have been consumed in its completion

The first volume of some 778 pages concerns itself with a complete description of the protozoa and with an inclusive exposition of the general life-history, physiology, and morphology of these organisms This section has undoubted importance from the point of view of systematic zoology Classification is always a vexatious subject, but it seems probable that the one adopted here may be accepted as a basis for further work A minute description of the various protozoa follows, special attention being given, as is their due, to parasitic and coprozoic forms Free-living forms are not, however, neglected The student of tropical medicine will read with especial interest the sections devoted to entamœbæ and the summary of our present knowledge of the trypanosomes of man and the lower animals The second volume contains descriptions of the coccidia which are parasitic to many forms of life, and the blood protozoa which are also included in the class sporozoa; the peculiar and pleomorphic malaria-like parasites of man, bats, birds, and the higher apes form an attractive subject for consideration The valuable summary on malaria, and the detailed information upon the anopheline carriers of this disease, deserve mention Part III. in the second volume deals with the spirochætes which are here boldly included with the protozoa, and, interlopers though they may be, they receive generous attention, which, in the lack of a standard account of the group, is opportune. Special features throughout the work are the quality of plates and the space given to technique by a proficient in the methods of investigation and culture of the protozoa A list of hosts, vertebrate and invertebrate, is included, and the accounts of the historic discoveries in protozoology appear to be accurate and complete, and even the somewhat hackneyed story of the life-cycle of the malaria parasite is readable The text is elucidated by 565 illustrations, mostly original and good, while of the 20 coloured plates those on the blood protozoa merit special praise There is a profuse bibliography

Oto-Rhino-Laryngology.

Handbuch der Hals- Nasen- Ohren-Heilkunde Edited by A Denker and O Kahler Sixth volume: Disease of the Ear, I. Berlin: Julius Springer; Munich J. F Bergmann 1926. Pp 1274 M 96

This is the first of the three volumes on diseases of the ear, which form part of Denker and Kahler's large text-book in nine volumes The first two volumes of the five devoted to the mouth and upper air passages have already appeared. The present issue maintains the high standard which characterised each of them.

The book opens with an account of the comparative anatomy of the ear, beginning with the static organs of invertebrates, and going on to describe the hearing apparatus of the vertebrates from cyclostomes and fishes upwards, and of the middle ear from amphibia to mammals Embryology is next discussed and is followed by a chapter on malformations of the human ear, and this in turn by a useful article on applied anatomy and a full description of the histology of all parts of the ear, and of the technique of the examination of these parts The second section of the book is concerned with the physiology of the ear; the mechanism of conduction of sound by air and by bone to the inner ear is discussed, together with the mode of action of the drum and ossicles Helmholtz's "resonance" theory of sound-perception is expounded in detail and Wilkinson's experiments with a working model are mentioned; other theories, such as Wrightson's, are not described The experimental investigation of the functions of the vestibules and semicircular canals is dealt with at some length

The rest of the volume comes under the heading of "Pathology and Therapy, General Section" In the chapter on ætiology the authors discuss the relationship of ear disease to the body in general the affections of the ear depending on disease of other organs and also the effects of syphilis, mumps, and the infectious diseases in general Chapters follow on general pathology, symptomatology and bacteriology Some of the subjects here mentioned would be more usefully treated under the descriptions of the particular diseases concerned, and the same criticism applies to the final chapter on general therapy The articles on clinical methods of examination are excellent. they include the methods of testing the vestibular apparatus and a full account of nystagmus Chapters on X ray examination, on serological methods, and a very useful one on lumbar puncture, which gives a full account of the various pathological changes in the cerebro-spinal fluid, complete this volume which, as a general survey, prepares the ground admirably for the other two volumes which will deal with the special diseases of the ear.

Handbuch der Neurologie des Ohres. Edited by Prof Dr. G Alexander and Prof Dr. O Marburg. Revised by Dr. H Brunner. Vol III. Berlin and Vienna: Urban and Schwarzenberg. 1926 Pp 825. M 60

This manual on the neurology of the ear is a large work produced by the collaboration of no less than 40 writers In this, the third, volume widely differing subjects are dealt with, which will have a varying degree of interest for the surgeon, the oculist, the aurist, the neurologist, and the general physician, all having as a common factor some connexion with the ear. In the first 150 pages Prof Marburg describes those tumours of the brain which come into relationship with the cochlear and vestibular apparatus—tumours, that is, especially of the cerebellum, cerebello-pontine angle, medulla and corpora quadrigemina These tumours are of great interest to the otologist as well as to the neurologist, and their characters and symptomatology are well and fully discussed Prof. Wolfgang Denk follows with a lucid account of the operative treatment of tumours of the brain, and Dr. M. Sgalitzer with a short description of the X ray treatment of diseases of the ear and cerebral tumours. The difficult subject of muscle tonus and dyskinesia is dealt with by Dr E. Pollak Other matters discussed in this volume include neurotic and hysterical affections of the cochlear and vestibular apparatus (in which it could be wished that more attention had been paid to the practical treatment of tinnitus and vertigo), traumatic neuroses of the ear, miners' nystagmus, sea-sickness, and spasmus nutans Nerve action and nerve disturbances in flying men are dealt with by Dr van Wulfften-Palthe and there is an interesting account by Dr E A Spiegel of experiments on the reflex effect of labyrinthine stimulation on the pupil, the vascular system, the heart respiratory system, and the alimentary tract Final chapters are on the influence of myxœdema and cretinism, and of other diseases of internal secretion, on the ear

From this short abstract of the contents of one of the three volumes, of which this work is composed, it will be seen that a great number of conditions come under consideration in dealing with the neurology of the ear The book is well produced, well illustrated where illustrations are needed notably in the article on tumours. and the authority of the subject matter is sufficiently attested by the names of the writers There is a full table of contents, an index, and an alphabetical list of the authorities quoted

Surgery of the Colon

By F W Rankin M D F.A.C S London and New York D. Appleton and Company 1926. Pp 366 21s

In this monograph the author deals exhaustively with the surgical conditions of the colon Whilst basing his statements upon the writings of others rather than upon his own personal experience he has succeeded in presenting clearly the views generally held by surgeons who have made this field a special study. The most valuable section of the book is that devoted to carcinoma and especially to the technical details of its surgical treatment. The last are thoroughly up to date and include several of the most modern methods of aseptic resection Illustrations here reach a high level Each section is accompanied by full statistics and bibliography, and the volume presents in a convenient form a vast amount of information on its subject

IMPERIAL SOCIAL HYGIENE CONGRESS.

Published by the British Social Hygiene Council, Inc, Carteret House, Carteret-street, London, S W. 1926 Pp. 300 4s

THE proceedings at the Imperial Social Hygiene Congress, held at the British Empire Exhibition in October of last year, have now been published by the British Social Hygiene Council, and the volume contains a collection of facts and experiences presented by doctors, administrators, and social workers from all parts of the Empire in connexion with the various problems of venereal disease and social hygiene as they arise at home and overseas The Congress gave an excellent opportunity, as could be gathered from the reports published at the time, for the interchange of opinion on many poignant matters, and Mr Amery, with whose opening address to the Congress the volume starts, deals with the imperial aspect of social hygiene, will find all medical men in agreement with his pronouncement that the administration of the empire as a whole, as well as the administration of this country, must be based on a sound health policy The addresses of delegates from the Crown Colonies, the Irish Free State, South Africa, New Zealand, Newfoundland, and India echo the same message, and prove that on fundamental questions of sanitation and prevention of disease our Colonial Office will have the various populations under their charge as supporters of hygienic reform

The volume contains important contributions, written out of practical experience, upon the position of the Army and Navy and mercantile marine with regard to venereal diseases, and upon the vast and various difficulties incurred in the treatment of venereal disease in India The problems in the Colonies, Protectorates, and Mandated Territories are mentioned cursorily, but many of the notes here, while they make terrible reading, prove that not only is the public conscience awakened all over the world, but that many sinister foci of disease have been detected and dealt with Sir Kingsley Wood, Parliamentary Secretary to the Ministry of Health, reviews the position with regard to venereal disease in Great Britain as well as in the self-governing Dominions, and is excellently supplemented in an exposition from Colonel L W. Harrison of what has been done in England and Wales during the nine years which have elapsed since the V D scheme was set up The effect of recent activities on the condition of affairs as disclosed by the report of the Royal Commission is remarkable, and no less remarkable are the lessons to be learnt from a study of the working of the scheme All medical men should read the debate on the position of venereal disease in Great Britain and the self-governing Dominions, when Sir Kingsley Wood was able to argue that between 1920 and 1924 there had been a fall of nearly 50 per cent of new cases of syphilis and of some 22 per cent. of new cases of gonorrhœa Colonel Harrison showed that the cost of the venereal disease scheme amounted to about 2½d per head of the population.

TROPICAL EQUIPMENT.

Hints on Equipment and Health for Intending Residents in the Tropics By J BALFOUR KIRK, M B, Ch B Edin, D.P H Oxf, D T M & H Eng London: Baillière, Tindall and Cox. 1926 Pp 120. 3s 6d

IN the form of a series of letters, written in colloquial style to fictitious characters of differing age and sex who contemplate visiting the tropics, Dr Balfour Kirk has effectively outlined the chief dangers to health that may be encountered. The modest volume contains sound advice, and its 18 chapters are worthy of detailed study. The subject matter covers the necessity of the preliminary medical examination and inoculations, the details of outfit, head covering, underwear, and special items of clothing to protect against mosquito infection Personal hygiene, dietary, and the abuse of alcoholic liquors are discussed, as

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 25, 1926.

THE PHYSIOLOGY OF POSTURE.

THE Cameron Prize Lectures delivered at the University of Edinburgh this year by Prof. RUDOLPH MAGNUS, of Utrecht, and published in the two last issues of THE LANCET, embody much that has already been made familiar to physiologists and clinicians in the pages of his fine volume, "Körperstellung." So complex are the physiological mechanisms implicated in the adoption and maintenance of body posture, so manifold and varied the reactions and inter-reactions of reflex arcs and somatic segments and parts of segments, that it is difficult for the newcomer to the subject to grasp the main principles amid a multiplicity of instances. In the Cameron Lectures Prof. MAGNUS has succeeded in the arduous task of concise yet sufficient exposition, avoiding the extremes alike of needless detail and of unsatisfying generalisation. If he does not in so many words draw conclusions which can be understood by all it is at the same time impossible to read these lucidly expressed lectures without gaining some knowledge of the general schemes whereby posture is regulated. Perhaps the student should first of all impress himself with the significance of the fact that in all of the experimental animals, of varying race and species, utilised for the purpose of posture investigation, the cerebral cortex is excluded—that is to say, the lecturer has obtained postural reactions of every conceivable kind in animals in which, according to all physiological evidence, volitional activity is literally nil. The highest type of experimental animal, the so-called "thalamus animal" (cerebral cortex, pyramidal tracts, and corpora striata being out of action) presents little, if any, recognisable differences from the intact animal when at rest; it appears quite at its ease, its attitudes and movements are not stiff or caricatured; but none the less it is no more than a physiological preparation, in the sense that its reactions are inevitable and systematised, and cannot be modified by volition. In such "thalamus animals," as well, of course, as in others where a greater degree of physiological severance has been effected, attitudes and postures can be elicited and sustained which have all the outward appearance of being smoothly produced—of being, so to say, normally developed—yet they are genuinely reflex, involuntary, automatic. These postures are just such as the intact animal exhibits and Prof. MAGNUS says it is interesting and instructive to observe their development and adoption in "ordinary" animals, the inference being that a large part of the motor activities of the latter is volitional only in appearance and is as a fact determined in a purely reflex fashion.

It would serve no useful purpose to attempt to summarise the long series of postural reactions discovered by Prof. MAGNUS and his collaborators, but some general considerations may be alluded to. When an animal is standing its position is maintained by no expenditure of voluntary effort but is reflexly brought about by the effect of stimuli from internal structures, mainly the muscles concerned (proprioceptive stimuli), and from external structures—e.g., the pads of the feet (exteroceptive stimuli). By means of what are called myotatic or stretching reflexes one muscle group so influences its neighbours and opposing groups that a limb is transformed from a mobile unit to a fixed muscular pillar for the purpose of sustaining body-weight; all is performed reflexly and automatically, and there can be little doubt that in man, analogously, the fixation of a limb, as in skating on the outside edge, follows reflex lines and does not entail the application of a stream of volitional impulses to the muscular groups concerned. When, again, an animal's equilibrium is upset it "rights" itself, a phenomenon that can readily be demonstrated in respect of the head only, or of the body, or of both of these, and this faculty of "righting" is proved to be of the nature of a purely reflex thing. The sensory end-organs concerned and the afferent paths and centres in the neuraxis are known. Thus when an animal is put on its side it will bring its head into the normal position: when the position of its head is altered movements of the body and limbs ensue, and so forth. No less than five sets of reflexes have been distinguished and separately studied, each one of which contributes its quota to the elaboration of the "righting" act. It is a fascinating study, this physiological dissection of the functions of the eyes, labyrinths, otoliths, neck tissues, and lateral end-organs of the body, in regard to the specific contribution each makes to the re-attaining of normal postures when such are disturbed. Prof. MAGNUS has begun by investigation of the reflexes of the spinal animal, then of the mid-brain animal, then of the thalamus animal, and by comparison of the additional reflex reactions obtainable in each of these successively more elaborate preparations he has been enabled to localise the neural centres, and, indeed, the exact anatomical units, for many of the postural activities involved. It would be almost impertinent to praise the infinite attention to detail, amounting to genius, which has resulted in this vast gain in precision and exactitude as far as our knowledge of the function of long familiar anatomical structures is concerned.

The lecturer does not, perhaps, take his reader far along the path toward the logical conclusion of these innumerable experiments, although an adumbration of the end to which they lead is clearly in his mind. We are told that 20 years have been devoted with success to research on the phenomena provided by the decerebrate animal (mid-brain level), and that the task of the immediate future is to investigate those of the thalamus animal with similar care. The result of the former has been to demonstrate beyond cavil that attitudinal as well as "righting" reactions are purely involuntary; in other words, much of what has hitherto seemed to be deliberate and volitional in respect of the animal's motor activity is shown to have another basis, and there is no sufficient reason to hesitate to apply the same conclusion to that of man. Subcortical mechanisms furnish for each new cortical action, without previous voluntary effort, "normal starting positions," says Prof. MAGNUS. If this is true in respect of the unrolling of potentialities of the mesencephalic animal how much more that is commonly thought to be voluntary may not in the event be shown to be a property of the thalamus animal whose cerebral cortex is out of action but which is in many ways seemingly "normal"? We must, naturally, be content with present progress, and not allow speculation to outrun the patient acquisition of data, but it is permissible to suppose, from what Prof. MAGNUS has already established, that volition may be eventually driven to the highest transcortical levels and that a part at least of cortical activity may be shown to be of an involuntary character. To this conclusion certain lines of evidence, derived from the study of human cases, most certainly point.

MATERNAL MORTALITY IN THE UNITED STATES.

In an article which we publish at the *front of this* issue, Dr G. W Theobald, who now occupies *the* Chair of Obstetrics in the Siamese capital, gives a disquieting account of the practice of midwifery in England and Wales as he saw it We at home may take what consolation we can, after admitting the shrewdness of his criticisms, *from the* knowledge that the same problems, producing similar conditions, are being faced abroad This will be gathered *from* a valuable report on maternal mortality and morbidity recently issued by the Children's Bureau of the Federal Government of the United States[1] This report is the work of Mr R M Woodbury, Ph D, formerly director of statistical research in the Bureau Regulations as to licensing of both doctors and midwives vary greatly in different parts of the country, and apart from the large centres of population there appears to be little supervision of the midwives' work, in one New England State midwives are not recognised by law. The great value of Dr Woodbury's report is that it puts before the Federal Government, the Governments of the 48 States, and the American people, the immensity of the problem with which they have to deal The report does not contain definite recommendations for legislation, probably because in the United States there are always two Governments to be considered—the Federal Government and the Government of each of the 48 States *In 1921* the registration area of the U S A covered 38 of these States, and included 82 2 per cent of the total population Dr Woodbury shows that even in the States included in this area there is a want of completeness in the registration of births and deaths, and there is little information forthcoming about midwives and their work Maternal mortality from childbirth in the United States, he affirms, is the highest in the civilised world In the table given in the report Chili comes second, New Zealand third, and Belgium fourth, the countries with the lowest mortalities being Denmark, the Netherlands, and Norway There is nothing encouraging in the figures which show the trend of the mortality during the present century, for although there is a considerable decline in the death-rate from puerperal septicæmia, this is almost balanced by an increase in the death-rate from other puerperal causes Analysis of the maternal deaths during the period shows that two-fifths were due to sepsis and about one-quarter to toxæmias Dr Woodbury believes that with a rigorously aseptic technique almost all deaths from sepsis could be prevented, and that with adequate antenatal care deaths from toxæmia might be practically eliminated Such antenatal care as is given is provided largely through hospitals in the large centres of population From the point of view of public health work, he considers, the problem of preventing puerperal mortality involves not only such general control over the licensing of doctors and midwives as shall ensure that they are properly trained, but also the provision of facilities for giving skilled medical attention and care to every woman who needs it This medical attention must be available during the antenatal, the natal, and the postnatal periods, and the mothers must be educated to demand competent medical supervision during pregnancy The Government, whether Federal or State, has four duties to perform in order that motherhood shall be protected (1) regulation of obstetrical practice, (2) licensing and inspection of public and private hospitals and *maternity* hospitals, (3) social hygiene legislation and the control of venereal diseases, and (4) notification of puerperal septicæmia These matters are dealt with in different ways by the various States, but the Federal Government is in a position to grant subsidies for the promotion of maternity and child welfare to any State which will accept the Sheppard-Towner Act This Act, which has now been accepted by 43 of the States, provides that no part of the Federal subsidies may be used for the purchase, rental, or maintenance of hospitals or other buildings, or for the payment of maternity allowances The intention of the Act is therefore especially to stimulate the appropriate State agencies to undertake educational work One of the noteworthy differences between the problem as it presents itself in the United States and in Great Britain is *the small part* as yet played in America by the midwives, in a large number of States the physicians attend 80 or 90 per cent of the registered births The question of colour and nationality of the mother is considered in the report, and it is pointed out, for example, that the Italian mothers usually prefer midwives, and that the coloured women have a heavier puerperal mortality, probably because they receive poorer medical and midwifery service Where a distinction is made between the attendance on white or coloured population in the various States there is a marked difference Thus in North Carolina 82 2 per cent of the white mothers were attended by a doctor and only 26 5 of the coloured Again, in Washington State only 1 4 per cent of white mothers were not attended by physicians as compared with 73 7 per cent of Japanese, 43 5 of Indians, and 14 9 of the other coloured women As is pointed out, however, the attendance of a physician does not necessarily ensure the best care, nor does that of a midwife necessarily mean the poorest, much depends on the qualifications and training of the particular physician or midwife A table dealing with the maternal mortality in 22 States in the birth registration area during 1919 gives the adjusted rate for the whole area as 7 7 per 1000 births, while the State rates vary from 11 7, 10 4, 9 9, and 9 5 in South Carolina, North Carolina, Oregon, and the district of Columbia, to 6 9, 6 7, 6 1, and 4 8 in Pennsylvania, Connecticut, Kentucky, and Wisconsin Dr. Woodbury estimates that the problem concerns the deaths of 20,000 mothers in the United States annually, and also affects the occurrence of 100,000 still-births and of 100,000 deaths of infants under the age of 1 month

◆

STREPTOCOCCAL TOXIN.

It is generally admitted that the results of the treatment of streptococcal infections by means of such antisera as are now available is as a *rule* very disappointing Why this should be so has until recently remained something of a mystery The explanation seems to have been provided by the work of the Dicks in America upon the streptococcus associated with scarlet fever Whether or *not* the streptococcus isolated by these workers is the *original* and only begetter of the disease still awaits conclusive proof, but quite apart from *this the researches* of the Dicks resulted in the disclosure *of one fact* of supreme importance *They* were *able to* obtain the toxin of their organisms in such a *state* that by the injection of it into animals they could produce a powerful antistreptococcal serum. Of the efficacy of the antiserum produced by the Dicks there can be no doubt. Its capacity for neutralising doses of toxin injected into the human skin, of blanching the scarlatinal rash and finally the results following its use in clinical scarlet fever all demonstrate that it is an agent of the same class as diphtheria antitoxin. The point of importance about this serum is that it is actually antitoxic and not anticoccal—that is to say, it is of the same nature as all the successful sera of which those used against diphtheria tetanus, and gas gangrene are the best examples

---

[1] Maternal Mortality By R. M. Woodbury, Ph D. Publication No 158 Issued by Children's Bureau of U S Department of Labour, from which single copies may be had free of charge

It has long been recognised that the streptococci produce a powerful toxin Thus it is an old observation that the serum obtained from the area of œdema around a cellulitis is sterile. None the less, the invasive power of the streptococcus has to some extent obscured its action as a toxin producer The preparation of a powerful antitoxin for therapeutic use has up to the present been successful only in the case of those organisms such as the *C diphtheriæ* and the *B tetani* whose invasive powers are so limited that in practice it is possible almost to ignore the focus of infection and to concentrate upon combating the generalised toxæmia. The invasive power of the streptococcus is great, but it is probable that extensive invasion only occurs when the way is prepared by the action of the toxin. The work of the Dicks, and much which has followed upon it, seem to indicate that the greater part of the tissue damage done by streptococcal infections is wrought by the toxin and does not follow upon the invasive power of the organism Given an efficient antitoxin it may be possible by neutralisation to prevent this toxic damage and by so doing actually to limit the spread of the organism. Up to the present the only definitely antitoxic streptococcal serum that has been produced is that against the *S. scarlatinæ* of the Dicks It is still doubtful how far this may be active against other strains of streptococci. In other words, the antigenic grouping of the streptococci is still more or less unknown. Many workers are engaged upon this problem at the moment, but from its complexity and the elaborate nature of the researches involved progress must necessarily be slow.

A valuable contribution to the subject is made by Sir Frederick Andrewes in the September number of *St. Bartholomew's Hospital Journal* Messrs. Burroughs and Wellcome produced for Prof. Andrewes toxins from two strains of hæmolytic streptococci, one obtained from a severe but not fatal infection in a nurse, the other being the organism responsible for the death of the late Dr Swann, which was one of the recent calamitous series following upon post-mortem infections among pathological workers in this country. Using these two toxins and a third American strain isolated from a case of erysipelas by Dr. K E. Birkhaug, Prof. Andrewes endeavoured to ascertain by their action upon the skins of normal persons whether or not they all fell into the same group Did they all fall into the same group it is obvious that their actions upon the skins of normal persons should all be the same This was found not to be the case. Some persons responded to one, some to another some to two out of three only, some to none, and so forth Of 48 persons tested only 26 gave the same reaction with all three toxins. This would seem to indicate that the toxins of the hæmolytic streptococci differ in their antigenic quality This must obviously complicate the problem of the preparation of an efficient antiserum; the next step and it may be a very long and difficult one, is to identify the commonly infecting strains of the hæmolytic streptococci. Once this has been achieved the preparation of an efficient antiserum should not prove a difficult matter. The whole of this work is of surpassing interest and importance. The toll which the streptococcus levels upon society is only too well recognised by the public, lay and medical alike There are few laymen who have not in their own experience known of some cases of severe possibly fatal "blood poisoning" following upon apparently trivial injury, and a monument in Westminster Abbey commemorates the lady-in-waiting to Queen Elizabeth who died after pricking her finger with her needle. Among doctors there can be few who have not frequently but vainly longed for some potent weapon against the streptococcus. That weapon is not yet to hand, but it seems that it is in the forging

"Ne quid nimis."

RHEUMATIC DISEASE IN CHILDHOOD

During the past year several investigations into the environment of cases of rheumatic heart disease in children have been carried out by members of the school medical service in different parts of the country. From his study of conditions in Bristol Dr. J. Morrison concludes that rheumatic heart disease in its origin is essentially a disease of the elementary school-child and although he finds no absolute connexion between rheumatic heart disease and poverty—the poorest of the poor are not the class most affected—the disease thrives where social and environmental conditions are worst. Most of the cases he investigated showed a family predisposition to rheumatism Chronic damp also appears to be of moment probably in the direction of lowering the resistance of the body in general to disease. When the situation of heart cases is plotted out on a map of Bristol they are seen to cluster around the many waters, opened and covered in, with which the centre of the city is inter-penetrated. But a little further consideration shows that these areas are, from developmental and economic reasons also the areas where the population is most dense and housing conditions least satisfactory. In London, too, children suffering from rheumatic heart disease are not distributed uniformly over the county area, but as Dr. Jean Shrubsall found many years ago, there are definite aggregations of cases along the lines of alluvial valleys marking the ancient courses of rivers such as the Hole Bourne or Fleet, the West Bourne, the Bridge Creek (Notting Dale), the Wandle, and the Effra. This inquiry has been repeated during the past year by Dr. F. C Shrubsall, whose diagram largely confirms the previous findings. The majority of rheumatic cases are found in the lower-lying districts near the Thames, where there is a densely populated area, particularly in the neighbourhood of the Neckinger in Bermondsey and Rotherhithe. Dr R. H. Vercoe's analysis of ætiological factors in Chelmsford is of special value because he has used controls in each case. His report appears substantially on p 669 of our present issue. Dr. Vercoe finds heredity to be the most important factor, with dampness following closely on it. Malnutrition as judged by height and weight and poor home conditions showed no definite relation to rheumatism. The same applied to septic teeth and enlarged tonsils. These conclusions differ somewhat from those of other investigators, and the explanation may be partly due to inclusion of many less severe cases In the *Birmingham Medical Review* last month Dr. A. P. Thomson gives an interesting spot-map of the distribution of cases in Birmingham, which closely resembles that seen in

MATERNAL MORTALITY IN THE UNITED STATES.

IN an article which we publish at the front of this issue, Dr G. W THEOBALD, who now occupies the Chair of Obstetrics in the Siamese capital, gives a disquieting account of the practice of midwifery in England and Wales as he saw it We at home may take what consolation we can, after admitting the shrewdness of his criticisms, from the knowledge that the same problems, producing similar conditions, are being faced abroad This will be gathered from a valuable report on maternal mortality and morbidity recently issued by the Children's Bureau of the Federal Government of the United States[1] This report is the work of Mr R M WOODBURY, Ph D, formerly director of statistical research in the Bureau Regulations as to licensing of both doctors and midwives vary greatly in different parts of the country, and apart from the large centres of population there appears to be little supervision of the midwives' work, in one New England State midwives are not recognised by law The great value of Dr WOODBURY's report is that it puts before the Federal Government, the Governments of the 48 States, and the American people, the immensity of the problem with which they have to deal The report does not contain definite recommendations for legislation, probably because in the United States there are always two Governments to be considered—the Federal Government and the Government of each of the 48 States In 1921 the registration area of the U S A covered 38 of these States, and included 82 2 per cent of the total population Dr WOODBURY shows that even in the States included in this area there is a want of completeness in the registration of births and deaths, and there is little information forthcoming about midwives and their work Maternal mortality from childbirth in the United States, he affirms, is the highest in the civilised world In the table given in the report Chili comes second, New Zealand third, and Belgium fourth, the countries with the lowest mortalities being Denmark, the Netherlands, and Norway There is nothing encouraging in the figures which show the trend of the mortality during the present century, for although there is a considerable decline in the death-rate from puerperal septicæmia, this is almost balanced by an increase in the death-rate from other puerperal causes Analysis of the maternal deaths during the period shows that two-fifths were due to sepsis and about one-quarter to toxæmias Dr WOODBURY believes that with a rigorously aseptic technique almost all deaths from sepsis could be prevented, and that with adequate antenatal care deaths from toxæmia might be practically eliminated Such antenatal care as is given is provided largely through hospitals in the large centres of population From the point of view of public health work, he considers, the problem of preventing puerperal mortality involves not only such general control over the licensing of doctors and midwives as shall ensure that they are properly trained, but also the provision of facilities for giving skilled medical attention and care to every woman who needs it This medical attention must be available during the antenatal, the natal, and the postnatal periods, and the mothers must be educated to demand competent medical supervision during pregnancy The Government, whether Federal or State, has four duties to perform in order that motherhood shall be protected (1) regulation of obstetrical practice, (2) licensing and inspection of public and private hospitals and maternity hospitals; (3) social hygiene legislation and the control of venereal diseases, and (4) notification of puerperal septicæmia These matters are dealt with in different ways by the various States, but the Federal Government is in a position to grant subsidies for the promotion of maternity and child welfare to any State which will accept the Sheppard-Towner Act This Act, which has now been accepted by 43 of the States, provides that no part of the Federal subsidies may be used for the purchase, rental, or maintenance of hospitals or other buildings, or for the payment of maternity allowances The intention of the Act is therefore especially to stimulate the appropriate State agencies to undertake educational work One of the noteworthy differences between the problem as it presents itself in the United States and in Great Britain is the small part as yet played in America by the midwives, in a large number of States the physicians attend 80 or 90 per cent of the registered births The question of colour and nationality of the mother is considered in the report, and it is pointed out, for example, that the Italian mothers usually prefer midwives, and that the coloured women have a heavier puerperal mortality, probably because they receive poorer medical and midwifery service Where a distinction is made between the attendance on white or coloured population in the various States there is a marked difference Thus in North Carolina 82 2 per cent of the white mothers were attended by a doctor and only 26 5 of the coloured Again, in Washington State only 1 4 per cent of white mothers were not attended by physicians as compared with 73 7 per cent of Japanese, 43 5 of Indians, and 14 9 of the other coloured women As is pointed out, however, the attendance of a physician does not necessarily ensure the best care, nor does that of a midwife necessarily mean the poorest, much depends on the qualifications and training of the particular physician or midwife A table dealing with the maternal mortality in 22 States in the birth-registration area during 1919 gives the adjusted rate for the whole area as 7 7 per 1000 births, while the State rates vary from 11 7, 10 4, 9 9, and 9 5 in South Carolina, North Carolina, Oregon, and the district of Columbia, to 6 9, 6 7, 6 1, and 4 8 in Pennsylvania, Connecticut, Kentucky, and Wisconsin Dr WOODBURY estimates that the problem concerns the deaths of 20,000 mothers in the United States annually, and also affects the occurrence of 100,000 still-births and of 100,000 deaths of infants under the age of 1 month

THE ARNETH COUNT

THE number of lobes of the polymorphonuclear leucocyte is subject to considerable variation, upon which fact Arneth based the technique by means of which he claimed to be able to derive some information as to the course of chronic infections Arneth in devising his technique proceeded upon the principle of Heidenhain, according to which the older a cell grows the smaller and the more convoluted becomes its nucleus He believed that the more adult cells that were present in the blood the better the powers of resistance would be Other workers elaborating Arneth's idea satisfied themselves that they had demonstrated that the multilobed and therefore older and more experienced polymorphs were better phagocytes than the single-lobed novices Much paper has flowed through the presses since Arneth published his technique, but although many and diverse workers have applied it to many and diverse conditions with equally manifold and diverse results, it is only lately that the technique has received a thorough critical investigation from the physiological standpoint This has been carried out by E Ponder and others working in the Department of Physiology of the University of Edinburgh, and the results appear in the *Quarterly Journal of Experimental Physiology* (vol. xvi, No 3) Ponder and his associates readily confirmed the almost universally held belief that the youngest form of the polymorph is that possessing an unlobed or two-lobed nucleus Taking advantage of the effect of injections of thyroid extract in causing polymorphs to be thrown out from the bone-marrow of the rabbit into the blood stream, they were also able to establish that it is in this single or two-lobed form that the vast majority of the polymorphs first make their appearance in the circulation They were further able to demonstrate that development into the four- or five-lobed forms takes place in the blood stream, and that it is as the four- or five-lobed forms that the bulk of the polymorphs make their disappearance from the circulation Up to this point the results of the investigation are in accordance with the principles of Heidenhain and the views of Arneth When, however, it came to the investigation of the comparative nuclear area of old and young cells it became apparent that the assumption that as the cells grow older and their nuclei become indented the nuclei also become smaller was incorrect No significant difference in size could be detected between young cells having a single-lobed nucleus and old cells with nuclei of many lobes Similarly, investigation of the comparative phagocytic activity of old and young cells failed to reveal any differences in their power of dealing with micro-organisms It was found that the Arneth count for healthy persons is remarkably constant for the individual, showing little variation over a term of years Pathological alterations did not come within the scope of the investigations, but it is evident that variations under conditions of ill-health in such an otherwise constant system may be of considerable clinical importance in conditions other than those to which Arneth first applied his technique

POISONING CASES IMMEDIATE TREATMENT AT HOSPITALS

UNDER this heading we commented last week upon an inquest, during the course of which Dr Edwin Smith, the coroner for North-East London, criticised the action of the house surgeon at the German Hospital, who had declined to treat a woman brought to the hospital suffering from lysol poisoning The evidence of the house surgeon was to the effect that the woman could not be admitted because no bed was available, and to the coroner's representation that first-aid should have been rendered—it may be added that the patient died shortly afterwards at the Metropolitan Hospital—the house surgeon replied that it would have taken some time to administer treatment, his institution not being duly equipped for such emergencies We were surprised at this statement, and are glad to be informed by the secretary to the German Hospital of the action taken by his Committee in view of the reports in the public press The Committee affirm, in a letter to the coroner, that their institution "is and always has been fully equipped for any emergency, including, of course, cases of poisoning Stomach pumps, antidotes, and emetics are not only in every consulting-room but also in every ward" As a consequence of the house surgeon's misleading evidence we learn that his services have been dispensed with There is, we understand, no suggestion that the life of the unfortunate woman would have been saved if she had been treated at once, but the Committee could do no other than call for the resident's resignation

INJECTION TREATMENT OF VARICOSE VEINS.

VARICOSE dilatation of the veins of the lower extremity is a common affection which exhibits great variation in the degree of disability to which it gives rise Frequently but little complaint is made, so that the patient is well advised to avoid direct treatment Often an elastic support will bring relief Surgical removal does not always free the patient from his symptoms, whilst distension of other veins sometimes occurs after it The direct surgical attack may be unfeasible, because of the complex network of dilated vessels widely spread over almost the whole limb below the knee There are, however, cases where obliteration of the internal saphenous vein is desirable and almost necessary When Trendelenburg's test demonstrates a column of blood unbroken by valves to extend from the heart to the region below the knee, it is, at any rate, a wise precaution to advise ligation and section of the internal saphenous vein at its upper extremity A few weeks ago we published a paper [1] by Sir Sidney Alexander, in which attention was called to an ambulatory method of treating varicose veins The obliteration of veins by the injection of a chemical substance is really a revival of an old procedure The history of the method has recently been told by Dr V Meisen, surgeon-in-chief to the Polyclinic at Copenhagen, who gives an

---

[1] THE LANCET, July 24th, p 176

London. He also states that rheumatism is not closely related to slum conditions. He is an advocate of tonsillectomy, done under ideal conditions, believing that this operation reduces the severity of rheumatism and limits the heart involvement. Dr Reginald Miller, on the other hand, in his report to the Science Committee of the British Medical Association, regards the effect of tonsillectomy as the removal of one factor predisposing to rheumatism and its routine performance as premature. His statement that in London rheumatism is a disease of hospital rather than of private practice—far more so than, for instance, pulmonary tuberculosis—deserves very close thought. For if we can ascertain why the infection is so common in the elementary schools and so rare in the preparatory and public schools, we should have gained a key position in our fight against the disease. In the same report Dr. Carey Coombs and Dr F J Poynton claim that there is no rival to the streptococcic theory of acute rheumatism, although there are certain difficulties which call urgently for a more extended inquiry by experienced bacteriologists. It is abundantly clear that the need of rheumatic children for prolonged care is as yet imperfectly realised in this country. Rheumatism, with its trail of death, maimed lives, and economic loss, is an insidious scourge which demands a concerted effort for its removal.

MENDELIAN VARIATION IN BACTERIA

IN two papers in the current number of the *Journal of Hygiene* (vol xxv, pp 237, 333) Dr F H Stewart, working at the Staffordshire Asylum at Cheddleton, returns to the study of the variations in the power to ferment sugars which may be observed to arise, and may be deliberately induced, in various members of the colon-typhoid group of bacteria. The brand of *Bacillus neapolitanus* which is known as *colon mutabile* does not ordinarily ferment lactose, and if it is plated out on neutral red agar containing lactose the colonies are white. Usually, however, after a while little red papillæ form in the centres of the colonies, and if these papillæ are plated out on to the same agar some colonies come up red and some white. The red colonies breed true and in the same environment always produce red colonies; the white colonies continue to produce red papillæ, which yield a mixture of red and white colonies. The corresponding phenomena are also seen if dulcite or cane sugar is substituted for lactose. And in general terms it is true, as Twort showed many years ago, that a bacillus can acquire the capacity of demonstrably fermenting a sugar by being grown in the presence of that sugar for a longer or shorter time, some organisms do it much more readily than others; some organisms apparently do not do it at all. The facts are obviously of great interest, both for the epidemiologist and the general biologist. Their interpretation is difficult and they have been discussed as examples of mutations, adaptive variations, acquired heritable characters, or possibly simple selection. Dr Stewart gives another explanation which we believe no one has had the courage to put forward seriously before, though many workers must have thought of the possibility and wondered if it was capable of demonstration. The changes in fermentative power which occur occasionally and casually (as in the paracolon race of *B neapolitanus*) he regards as mutations in De Vries's sense. But where, as in the *mutabile* race, the change takes place regularly and uniformly, he takes it to be a straightforward segregation of Mendelian factors. Mutabile is heterozygous, non-fermentation of lactose—i e, white colonies—being dominant; it has the formula IiFF, where F is the factor for the fermentation of lactose, I a factor which inhibits F, and i the absence of I. On ordinary media this goes on without change, in media containing lactose some of the descendants lose I and with a formula iiFF are able to ferment lactose and grow as red colonies; others continue as IiFF, while the pure dominant homozygotes IIFF fail to grow in competition with the other forms. Dr Stewart explains in the same way the appearance of other variations in fermentation and of the capsulated forms which often are more virulent than normal, and in his second paper draws an analogy between the inhibiting factor and an internal secretion.

There are many difficulties in accepting his view of the facts. We do not know whether bacteria have a sexual cycle or not, and we cannot (or do not) trace the descendants of individuals. The further knowledge of reproduction in the higher fungi progresses, the more likely does it seem that bacteria will ultimately be found to have some method of reproduction equivalent to a sexual process, and that the products of such a process may exhibit segregation of characters. But at present nothing certain can be based on any such expectations. And while Dr Stewart's explanation will, as he says, fit his facts fairly well, it is equally true that any set of genetical facts can be explained by a sufficient number of assumptions in respect of environmental inhibiting and lethal factors and variable dominance. These assumptions he makes very freely. For each of them there are established analogies, but the theory as a whole rests on a slender basis. It postulates somatic segregation (as in the derivation of the nectarine from the peach), the production of recessive mutations by environment (as in Harrison's melanic moths) of a kind which are adapted to the environment and non-viable dominants (as in yellow mice), it is also necessary to assume non-viable recessives (for which there are many analogies) if *mutabile* on ordinary media is really a heterozygote. On such terms it is possible to explain almost anything. Technically, such experiments ought to begin with a single cell isolated with all the certainty which is available. Dr Stewart seems to have taken no particular precautions about the purity of his cultures.

THE CONSTRUCTION OF HOSPITALS

So many hospitals are being rebuilt, enlarged, or remodelled, and so many new ones are projected, that the Memorandum on the Construction of Voluntary Hospitals which has just been issued by the Voluntary Hospitals Commission (H M Stationery Office, 2*d*) will serve an exceedingly useful purpose. Hospital architecture, like most other things connected with hospitals, is in a difficult stage of transition. Most human affairs generally are in this stage, though mankind is often unwilling to recognise that the law of its being is opposed to the static condition. How little likelihood there is of standing still where hospitals are concerned is brought home to us, almost alarmingly, by the Voluntary Hospitals Commission's definition of a permanent hospital as "a building expected to be required for 25 or 30 years." When we regard the age of a very large proportion of hospital buildings, the phrase suggests either that the Commission is a very advanced and enlightened body or that the country is very backward in its theories and practice. The latter is, undoubtedly, the real situation, though it must be remembered that what we may call the true hospital creed is not much more than ten or a dozen years old. The Great War, and all that flowed from it, the rapidity of the growth of the hospital idea, the astonishing progress in the scientific study of disease, and especially in the means and methods of preventing it, have combined radically to alter the public conception of the place of the hospital in modern life. The consequence is not only that most hospitals have become too small for the demands upon them, but that many are so constructed, arranged, and equipped that they are incapable of meeting requirements that are constantly growing more numerous and more complex. During the next decade or two, therefore, there must necessarily be vigorous activity in the erection of new buildings and the costly improvement of old ones. It will often be relatively as cheap, when all aspects of the subject are considered, to build afresh and on a new site as to tinker, perhaps even then without safeguarding the future This Memorandum, though necessarily suggestive and tentative rather than axiomatic, contains abundant material for forming a judgment upon what should be done in a particular case It shows the importance of such matters as situation, aspect, area, accessibility, the nature of the soil, and other considerations which were often airily disregarded by the old hospital builders The danger of being hemmed in or of the creation of factories in the immediate vicinity has to be guarded against The buildings must be so disposed that the wards and service departments will obtain every possible ray of sunshine The comfort and convenience of the staff, from the medical officers to the scullery maids, are, in their way not less important than the most effective disposition of the wards The saving of time and trouble are of cardinal moment in a hospital Without pretending to be detailed or exhaustive the Memorandum is sufficiently specific upon important practical points, such as the size and height of wards, the nature of walls and floors, and the width of stairs, as to afford an almost indispensable guide to those who are responsible for the plans of new hospital buildings The Commission's hints, suggestions, and recommendations embody the fruits of recent experience in a simple and accessible form, and among those recommendations will be noticed a decided preference for the pavilion form and for buildings of not more than three storeys These are matters in which English and American practice differ and in which there is no positive right or wrong Circumstances must everywhere be the governing factor

THE ARNETH COUNT

THE number of lobes of the polymorphonuclear leucocyte is subject to considerable variation, upon which fact Arneth based the technique by means of which he claimed to be able to derive some information as to the course of chronic infections Arneth in devising his technique proceeded upon the principle of Heidenhain, according to which the older a cell grows the smaller and the more convoluted becomes its nucleus He believed that the more adult cells that were present in the blood the better the powers of resistance would be Other workers elaborating Arneth's idea satisfied themselves that they had demonstrated that the multilobed and therefore older and more experienced polymorphs were better phagocytes than the single-lobed novices Much paper has flowed through the presses since Arneth published his technique, but although many and diverse workers have applied it to many and diverse conditions with equally manifold and diverse results, it is only lately that the technique has received a thorough critical investigation from the physiological standpoint This has been carried out by E Ponder and others working in the Department of Physiology of the University of Edinburgh, and the results appear in the *Quarterly Journal of Experimental Physiology* (vol xvi , No 3) Ponder and his associates readily confirmed the almost universally held belief that the youngest form of the polymorph is that possessing an unlobed or two-lobed nucleus Taking advantage of the effect of injections of thyroid extract in causing polymorphs to be thrown out from the bone-marrow of the rabbit into the blood stream, they were also able to establish that it is in this single or two-lobed form that the vast majority of the polymorphs first make their appearance in the circulation They were further able to demonstrate that development into the four- or five-lobed forms takes place in the blood stream, and that it is as the four- or five-lobed forms that the bulk of the polymorphs make their disappearance from the circulation Up to this point the results of the investigation are in accordance with the principles of Heidenhain and the views of Arneth When, however, it came to the investigation of the comparative nuclear area of old and young cells it became apparent that the assumption that as the cells grow older and their nuclei become indented the nuclei also become smaller was incorrect No significant difference in size could be detected between young cells having a single-lobed nucleus and old cells with nuclei of many lobes Similarly, investigation of the comparative phagocytic activity of old and young cells failed to reveal any differences in their power of dealing with micro-organisms It was found that the Arneth count for healthy persons is remarkably constant for the individual, showing little variation over a term of years Pathological alterations did not come within the scope of the investigations, but it is evident that variations under conditions of ill-health in such an otherwise constant system may be of considerable clinical importance in conditions other than those to which Arneth first applied his technique

POISONING CASES IMMEDIATE TREATMENT AT HOSPITALS

UNDER this heading we commented last week upon an inquest, during the course of which Dr Edwin Smith, the coroner for North-East London, criticised the action of the house surgeon at the German Hospital, who had declined to treat a woman brought to the hospital suffering from lysol poisoning. The evidence of the house surgeon was to the effect that the woman could not be admitted because no bed was available and to the coroner's representation that first-aid should have been rendered—it may be added that the patient died shortly afterwards at the Metropolitan Hospital—the house surgeon replied that it would have taken some time to administer treatment, his institution not being duly equipped for such emergencies We were surprised at this statement, and are glad to be informed by the secretary to the German Hospital of the action taken by his Committee in view of the reports in the public press The Committee affirm in a letter to the coroner that their institution " is and always has been fully equipped for any emergency, including, of course, cases of poisoning Stomach pumps, antidotes, and emetics are not only in every consulting-room but also in every ward " As a consequence of the house surgeon's misleading evidence we learn that his services have been dispensed with There is, we understand, no suggestion that the life of the unfortunate woman would have been saved if she had been treated at once, but the Committee could do no other than call for the resident's resignation.

INJECTION TREATMENT OF VARICOSE VEINS

VARICOSE dilatation of the veins of the lower extremity is a common affection which exhibits great variation in the degree of disability to which it gives rise Frequently but little complaint is made, so that the patient is well advised to avoid direct treatment Often an elastic support will bring relief Surgical removal does not always free the patient from his symptoms, whilst distension of other veins sometimes occurs after it The direct surgical attack may be unfeasible, because of the complex network of dilated vessels widely spread over almost the whole limb below the knee There are, however, cases where obliteration of the internal saphenous vein is desirable and almost necessary When Trendelenburg s test demonstrates a column of blood unbroken by valves to extend from the heart to the region below the knee. it is, at any rate, a wise precaution to advise ligation and section of the internal saphenous vein at its upper extremity A few weeks ago we published a paper [1] by Sir Sidney Alexander, in which attention was called to an ambulatory method of treating varicose veins The obliteration of veins by the injection of a chemical substance is really a revival of an old procedure The history of the method has recently been told by Dr V Meisen, surgeon-in-chief to the Polyclinic at Copenhagen, who gives an

London. He also states that rheumatism is not closely related to slum conditions. He is an advocate of tonsillectomy, done under ideal conditions, believing that this operation reduces the severity of rheumatism and limits the heart involvement. Dr. Reginald Miller, on the other hand, in his report to the Science Committee of the British Medical Association, regards the effect of tonsillectomy as the removal of one factor predisposing to rheumatism and its routine performance as premature. His statement that in London rheumatism is a disease of hospital rather than of private practice—far more so than, for instance, pulmonary tuberculosis—deserves very close thought. For if we can ascertain why the infection is so common in the elementary schools and so rare in the preparatory and public schools, we should have gained a key position in our fight against the disease. In the same report Dr. Carey Coombs and Dr. F. J. Poynton claim that there is no rival to the streptococcic theory of acute rheumatism, although there are certain difficulties which call urgently for a more extended inquiry by experienced bacteriologists. It is abundantly clear that the need of rheumatic children for prolonged care is as yet imperfectly realised in this country. Rheumatism, with its trail of death, maimed lives, and economic loss, is an insidious scourge which demands a concerted effort for its removal.

MENDELIAN VARIATION IN BACTERIA

IN two papers in the current number of the *Journal of Hygiene* (vol. xxv., pp. 237, 333) Dr. F. H. Stewart, working at the Staffordshire Asylum at Cheddleton, returns to the study of the variations in the power to ferment sugars which may be observed to arise, and may be deliberately induced, in various members of the colon-typhoid group of bacteria. The brand of *Bacillus neapolitanus* which is known as *colon mutabile* does not ordinarily ferment lactose, and if it is plated out on neutral red agar containing lactose the colonies are white. Usually, however, after a while little red papillæ form in the centres of the colonies, and if these papillæ are plated out on to the same agar some colonies come up red and some white. The red colonies breed true and in the same environment always produce red colonies, the white colonies continue to produce red papillæ, which yield a mixture of red and white colonies. The corresponding phenomena are also seen if dulcite or cane sugar is substituted for lactose. And in general terms it is true, as Twort showed many years ago, that a bacillus can acquire the capacity of demonstrably fermenting a sugar by being grown in the presence of that sugar for a longer or shorter time; some organisms do it much more readily than others, some organisms apparently do not do it at all. The facts are obviously of great interest, both for the epidemiologist and the general biologist. Their interpretation is difficult and they have been discussed as examples of mutations, adaptive variations, acquired heritable characters, or possibly simple selection. Dr. Stewart gives another explanation which we believe no one has had the courage to put forward seriously before, though many workers must have thought of the possibility and wondered if it was capable of demonstration. The changes in fermentative power which occur occasionally and casually (as in the paracolon race of *B. neapolitanus*) he regards as mutations in De Vries's sense. But where, as in the *mutabile* race, the change takes place regularly and uniformly, he takes it to be a straightforward segregation of Mendelian factors. Mutabile is heterozygous, non-fermentation of lactose—i.e., white colonies—being dominant; it has the formula IiFF, where F is the factor for the fermentation of lactose, I a factor which inhibits F, and i the absence of I. On ordinary media this goes on without change; in media containing lactose some of the descendants lose I and with a formula iiFF are able to ferment lactose and grow as red colonies; others continue as IiFF, while the pure dominant homozygotes IIFF fail to grow in competition with the other forms. Dr. Stewart explains in the same way the appearance of other variations in fermentation and of the capsulated forms which often are more virulent than normal, and in his second paper draws an analogy between the inhibiting factor and an internal secretion.

There are many difficulties in accepting his view of the facts. We do not know whether bacteria have a sexual cycle or not, and we cannot (or do not) trace the descendants of individuals. The further knowledge of reproduction in the higher fungi progresses, the more likely does it seem that bacteria will ultimately be found to have some method of reproduction equivalent to a sexual process, and that the products of such a process may exhibit segregation of characters. But at present nothing certain can be based on any such expectations. And while Dr. Stewart's explanation will, as he says, fit his facts fairly well, it is equally true that any set of genetical facts can be explained by a sufficient number of assumptions in respect of environmental inhibiting and lethal factors and variable dominance. These assumptions he makes very freely. For each of them there are established analogies, but the theory as a whole rests on a slender basis. It postulates somatic segregation (as in the derivation of the nectarine from the peach), the production of recessive mutations by environment (as in Harrison's melanic moths) of a kind which are adapted to the environment and non-viable dominants (as in yellow mice); it is also necessary to assume non-viable recessives (for which there are many analogies) if *mutabile* on ordinary media is really a heterozygote. On such terms it is possible to explain almost anything. Technically, such experiments ought to begin with a single cell isolated with all the certainty which is available. Dr. Stewart seems to have taken no particular precautions about the purity of his cultures.

THE CONSTRUCTION OF HOSPITALS

So many hospitals are being rebuilt, enlarged, or remodelled, and so many new ones are projected, that the Memorandum on the Construction of Voluntary Hospitals which has just been issued by the Voluntary Hospitals Commission (H.M. Stationery Office, 2*d.*) will serve an exceedingly useful purpose. Hospital architecture, like most other things connected with hospitals, is in a difficult stage of transition. Most human affairs generally are in this stage, though mankind is often unwilling to recognise that the law of its being is opposed to the static condition. How little likelihood there is of standing still where hospitals are concerned is brought home to us, almost alarmingly, by the Voluntary Hospitals Commission's definition of a permanent hospital as "a building expected to be required for 25 or 30 years." When we regard the age of a very large proportion of hospital buildings, the phrase suggests either that the Commission is a very advanced and enlightened body or that the country is very backward in its theories and practice. The latter is, undoubtedly, the real situation, though it must be remembered that what we may call the true hospital creed is not much more than ten or a dozen years old. The Great War, and all that flowed from it, the rapidity of the growth of the scientific hospital idea, the astonishing progress in the means and study of disease, and especially in the methods of preventing it, have combined radically to alter the public conception of the place of the hospital in modern life. The consequence is not only that most hospitals have become too small for the demands upon them, but that many are so constructed, arranged, and equipped that they are incapable of meeting requirements that are constantly growing more numerous and more complex. During the next decade or two, therefore, there must necessarily be vigorous activity in the erection of new buildings and the costly improvement of old ones. It will often be relatively as cheap, when all aspects of the subject are considered, to build afresh and on a new site as industrial conditions much accentuated lately by trade depression and the shortage of suitable investigators available. Attention is called to the many openings which will arise in future for those with scientific training to take up work of this kind.

NATIONAL INSTITUTE FOR THE DEAF.

AT the second annual meeting of the Council of the National Institute for the Deaf (formerly the National Bureau for Promoting the General Welfare of the Deaf) certain resolutions were passed,[1] and the Committee of the Institute have now prepared and circularised for consideration and criticism a memorandum dealing with the present position and the possible promotion of means to give the deaf population better opportunities of becoming self-supporting The Committee points to the weakness of existing organisation with the following statement .—

> (a) The incidence of societies is markedly uneven and accidental. Large parts of the country are not provided for, while in some cases there is overlapping
>
> (b) There is no equality of welfare effort. The efficiency of the service varies in different areas and even in different parts of the same area.
>
> (c) There is a general insufficiency in the staffs available for the work.
>
> (d) The funds available for the service are generally insufficient
>
> (e) There are no general training facilities for the welfare worker There is no coördination between the 50 existing societies no regular or efficient means of conference and no provision for recording general experience and statistics. The result is that there is an absence of national ideals and a serious lack of corporate action to advance the general cause of the deaf.

It will be seen at once that if the funds, whose absence is noted, were forthcoming, the other defects would soon disappear under the energy now being displayed by the Institute. The existing welfare agencies have cognisance probably of less than half the 40,000 deaf-born persons in the country, while in great areas there is a total lack of provision for dealing with the problems We have received the last annual report of the Institute, from which it is clear that to maintain the important work already done and doing and to extend its usefulness much more money is required For this purpose an appeal is about to be launched, and it is worthy of medical support, for, apart from those medical men who are specially interested in the welfare of the deaf, all practitioners in the course of their work have come across deaf subjects, not necessarily patients whose future is a great source of anxiety In some of these cases the mental condition should be properly estimated ; in others arrangement is needed for their education : yet again in others organisation is required to assist them to obtain posts which despite their physical drawbacks they could fill satisfactorily. We hope, in this last connexion, that the full returns of the inquiry into the industrial conditions of the deaf, which is now in progress, will shortly be available

THE MEDICAL DEFENCE UNION

THOSE who read the annual report for 1925 of the Medical Defence Union must be struck by the value of the work it records, and must wonder again at the temerity of medical men who do not join any protective society It is a tradition amongst money-lenders that doctors are easily deceived and undoubtedly there are many of them who believe that as long as they do their duty the law will never let them down Unfortunately, this is far from true Every practitioner runs a constant risk at the hands of cantankerous or misguided patients, and a good defence may not save him from financial loss Last year for instance a charge of negligence was brought against a medical man by a patient who was earning but a few pounds a week. The costs of defending the action amounted to over £500 and although the doctor won the case, he could never have recovered a penny of his £500, and would have been that amount to the bad if he had not been a member of the Medical Defence Union which bore the whole cost for him. Innocence, even nowadays, may be as expensive as guilt and members of a vulnerable profession ought to protect themselves when it can be done so cheaply by joining the Medical Defence Union or a kindred society. By so doing they gain skilful advice and unlimited indemnity in cases which the Union can defend, and they need never be forced, by lack of funds into making settlements out of court—a necessity which may adversely affect other doctors, by encouraging litigious or unscrupulous people to similar efforts The affairs of the Union are in a very satisfactory state and the membership had risen to 12,976 by the end of last year The annual report is worth reading because it discusses a number of questions which may at any moment become acutely important to practitioners The responsibility of doctors for the acts of their locum tenents and assistants is again considered and the recommendation renewed that such representatives should be persuaded themselves to join a protective society Time-worn but ever necessary advice is given about the need for radiography in every case of injury where bones or joints may be involved, and the usual warning against taking action before consulting the Union is reiterated Referring to appeals to the Ministry of Health against decisions by insurance committees, the Union's solicitors make the following reassuring comment .—

> "We have frequently heard members of the profession criticise the appellate provisions contained in the Insurance Acts and the nature of the tribunal to which the appeal is made, but in justice, we feel that we ought to say that, in our experience appeals are conducted with the utmost fairness, and that the facilities now provided under the Insurance Acts ensure a full and impartial inquiry by skilled and trained officers The only criticism we have to make is with regard to the amount awarded in point of costs, as, even where costs are awarded to a successful party these are seldom anything like sufficient to defray the expenses involved and frequently prove to be irrecoverable."

Besides defending its own members the Union aims at protecting the interests of the profession as a whole and also of the public To this end it takes action against irregular practice, where this can be brought within the limited scope of the penal sections of the Medical Acts and it brings suitable cases to the notice of the General Medical Council The solicitors find it a matter of surprise how little the functions of the Council are understood by the ordinary practitioner and their report endeavours to clear up some of these misunderstandings. The Union has always done its best to discourage litigation or disputes between members of the profession and is always prepared to lend its aid to the settlement of disputes between practitioners Arbitrators have been from time to time appointed in order to prevent cases going into court and this arrangement can be of great service to the profession

HISTORY OF THE ROYAL SANITARY INSTITUTE.

DR Louis C Parkes Vice-President of the Royal Sanitary Institute, has written a worthy account[1] of a body doing very valuable work The Institute had its origin in a discussion at the meeting of the Social Science Congress in 1876 after which Dr. Lory Marsh caused an advertisement to be inserted in THE LANCET and *The Sanitary Record* setting forth suggestions for its establishment The objects proposed were as follows · To provide a central place account[2] of his own experimental and clinical observations He has discarded the use of mercurial solutions, carbolic acid, or acetone, finding that he gets the best results with a 20–30 per cent solution of sodium salicylate Experimentally he finds in the horse that such injections cause almost instantaneous clotting and the thrombus is very firmly attached to the wall of the vein Inflammatory changes occur in the vessel wall and organisation of the clot soon takes place In the treatment of varicose veins Meisen deprecates confinement to bed during the injections The whole duration of the treatment may extend over a number of weeks, as multiple injections at intervals of 3–4 days may be necessary His results in 43 cases have been ultimately satisfactory There are difficulties and drawbacks to the method In five patients an ascending chemical phlebitis was set up, causing a little anxiety, but in all of them the trouble promptly subsided with rest The incidence and course of this complication are obviously important factors to be considered in appraising the value of the method Injections above the lower third of the thigh are not recommended In one patient high temperature and rigors followed injection in the presence of eczema and were probably septic in origin Intractable ulcers have been made to heal by injecting the neighbouring dilated veins An unpleasant complication is the formation of a slough at the site of the puncture, owing to escape of some of the hypertonic solution into the subcutaneous tissue. To avoid it the tissues in the neighbourhood of the injected vein are infiltrated, after the salicylate has been used, with normal saline solution Ulcers which occur in this way are to be avoided as they take months to heal On the whole the very detailed and careful work at Copenhagen is favourable to the method, but it would certainly appear advisable to proceed with caution before recommending its general adoption as a routine, for it seems that in other hands less familiar with the technique complications have been more frequent than after the usual surgical ligature and excision operation.

PROLONGED NARCOSIS IN PSYCHIATRY.

READERS of medical literature are familiar with certain forms of treatment which produce good results, though the modus operandi is obscure Examples of such empirical methods are the use of malaria in paresis, or the injection of bodies which produce a leucocytosis, accompanied with more or less severe local and general reactions Recently assault upon established psychoses has been attempted by producing a prolonged state of drowsiness, or even sleep Some promising results have been published, and it is possible that something is to be hoped from this method of treatment Numerous drugs have been used for producing the prolonged sleep—morphine, hyoscine, bromides, and other established hypnotics among them In this country little use has been made of somnifen, which is a mixture of the di-ethylamine salt of di-ethyl-barbituric acid and allyl-iso-propyl-barbituric acid prepared in a Swiss laboratory, but the drug has been extensively tested in Switzerland by Hediger and some of his pupils, who report encouraging results Major O A R Berkeley-Hill, of the Indian Medical Service, in a series of three cases, did not find the results particularly successful The technique is not easy The drug is given intravenously or intramuscularly, and produces a deep sleep which lasts for a number of hours When consciousness partly returns the patient is given another dose, which ensures a further period of sleep Care must be taken to see that the bowels and urine are attended to, in many cases artificial feeding, catheterisation, and enemata being required. The period of sleep is prolonged for several days, the Swiss physicians continue it for ten days or more But the longer the treatment the more definite the risk, and since fatalities have occurred it is the wiser plan to try a period of five or six days at first, when if improvement follows a second period of narcosis can be induced Careful nursing is essential, during the treatment the temperature must be watched and the injections discontinued if a sharp rise takes place The type of case which benefits has not as yet been clearly defined, although the schizophrenoid group, confusional states, and anxiety conditions seem suitable for trial Schizophrenoid cases wake clearer and freer from hallucinations but tend to relapse under stress of ordinary life The chronic course of mental disease renders any avenue of treatment which offers a reasonable prospect of success worthy of careful exploration

INDUSTRIAL FATIGUE

THE sixth annual report[1] of the Industrial Fatigue Research Board, which makes its appearance as we are going to press, covers the period up to Dec 31st, 1925, and includes an admirable summary of work already published Further investigation into problems of wide industrial importance showed that a spell of work broken by a short rest is more effective than an unbroken spell of the same length, while rest pauses not only reduce monotony and increase contentment, but result in a genuine increase in the rate of output Inquiry into the causation of accident led to belief in the ultimate possibility of indicating in advance persons having a special susceptibility to accident The speed with which skill can be acquired in different types of occupation has been systematically studied, but the inquiry has come up against the great difficulty of obtaining reliable data under actual factory conditions, and it is to be continued in the laboratory A study in vocational guidance, published in collaboration with the National Institute of Industrial Psychology, has established the greater stability of employment and greater contentment with conditions of work in a group of children placed in occupations which the tests indicated as suitable for them Problems submitted by Government departments to the Board have included an analysis of sickness in cotton-weaving sheds and the determination of the actual load that can be lifted or carried by women or young workers without injury or discomfort Laboratory work carried out at University College, London, suggests that lactic acid may be regarded as a governor of oxidation in the body during muscular work and that carbohydrate is the primary fuel of muscle A remarkable investigation into violent athletic effort revealed an oxygen requirement of about ten times the normal during a short sprint At Guy's Hospital the tests for physical fitness have been continued, especially in relation to the disability of cardiac cases At Cambridge attention has been given to the efficiency of instruction in regard to the type of mental imagery of the taught, the result varying according to whether the given person is a visualiser or an audile Work continued at Glasgow has afforded no evidence that healthy women are rendered physiologically ineffective during the menstrual period At Manchester the psycho-galvanic reflex has been further studied In view of the results obtained by many groups of investigators up to the present time Mr William Graham, chairman of the Board, remarks that the time is fast approaching when the scientific study of the human factor in industry will no longer be regarded as a praiseworthy attempt to benefit a few individual workers, but will be accepted as the beginning of a movement with limitless possibilities in which industry itself must participate The Board has no longer any doubt that the well-being of the worker and his productive efficiency can be definitely increased by finding and adopting the most favourable conditions and methods of work Immediate obstacles to the work of the Board are the unexpected variations in

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation on the Treatment of Medical and Surgical Conditions

CXC—THE TREATMENT OF HALLUX VALGUS AND HALLUX RIGIDUS

Nature and Causation of Hallux Valgus

Hallux valgus consists essentially of a lateral deviation of the big toe towards the middle line of the foot at the metatarsophalangeal joint A deviation of the terminal joint of the big toe in the same direction is not unusual and should not be termed a hallux valgus, as it does not give rise to the same symptoms or disability. Sooner or later a hallux valgus deformity gives rise to the following secondary conditions to which the actual symptoms are due

1 The articular surface of the phalanx ceases to articulate with the whole of the metatarsal, leaving an uncovered boss of bone projecting on the inner side of the foot. The articular surface of the head of the metatarsal becomes grooved its outer part continuing to form part of the joint, its inner part forming a prominence, often called an exostosis This projecting bone gradually becomes enlarged and thickened as the result of chronic inflammatory change and gives rise to the next train of symptoms

2 Over the bony prominence a pad and bursa develop On dissection it will often be found that this bursa communicates with the joint, and that there is also a large amount of new fibrous tissue attached to the head of the metatarsal. The skin over this pad and bursa develops callosities and sometimes a true corn. Much of the pain of hallux valgus is due to friction or local pressure upon a bursa and upon the callosity overlying it.

3. Recurring attacks of inflammation in the bursa and in the skin overlying it may eventually result in suppuration of the bursa, which may subside after incision and drainage, but often leaves an intractable sinus.

4. Apart altogether from suppuration a secondary arthritis with production of new bone around the head of the metatarsal and stiffening of the joint is not uncommon in an old-standing hallux valgus.

5 Owing to the lateral deviation of the big toe the second toe may be lifted completely off the ground and lie on the top of the phalanges of the big toe. Often, however, there is a coexisting hammer-toe, which lies in between the proximal phalanges of the big toe and the third and which is compressed and rendered more deformed by the increasing deviation of the big toe.

6 Nearly always the feet become widened across the region of the metatarsal heads, the transverse arch is lost, and the head of the second metatarsal comes heavily on the ground and takes more weight than does the head of the first. A callosity, which may be very painful develops in this situation and may, in fact, constitute the patient's chief complaint. Clawing up of the other toes with complete loss of the transverse arch of the foot is quite common.

Ætiological Factors

Among the ætiological factors of hallux valgus must be included a congenital tendency, since the condition is found occasionally in childhood. usually associated with a hammer (second) toe. Pressure by boots and shoes is however, the most important cause Severe degrees of hallux valgus are far more common in women than in men, and this must be ascribed to the type of shoe worn.

Tight shoes which exert a lateral pressure upon the toes beyond the metatarsal heads are an important factor; in these shoes the upper is often much wider than the sole, so that the region of the metatarsal heads can bulge at the sides over the sole, the toes being tightly compressed. The shoe is also brought to a point underneath its middle, so that the inner border is not nearly straight, but convex inwards. Another important factor in the shape of the shoe is the pitch of the heel, the surface of which should be approximately parallel with the ground. In many shoes with heels of 1½ in. or more in height, the heel slopes downwards and forwards, so that the foot tends to slide forwards into the toe of the shoe, and even when the shoe is apparently quite large the toes tend to get compressed. This compression not only acts mechanically in causing a deviation of the big toe but also interferes with the use of the intrinsic muscles of the foot and, by throwing the abductor hallucis out of action, prevents the natural effort to correct the hallux valgus The fit along the inner border of the shoe is a further factor in increasing the deformity. In most women's shoes it will be found that the leather is not close up to the foot behind the head of the first metatarsal The result is local pressure upon the prominent joint without corresponding support behind it, and this local pressure increases the development of new bone and causes continuous irritation.

In many cases of hallux valgus the longitudinal arch of the foot is flattened and the foot is in a valgus position, the patient walking on the inner border. This additional pressure against the inner side of the big toe tends to increase the deformity.

Nature and Causation of Hallux Rigidus

Hallus rigidus consists of a chronic arthritis of the metatarsophalangeal joint of the big toe with the production of much new bone. mainly around the head of the metatarsal but also to a less extent around the base of the phalanx.

The head of the metatarsal is altered in shape, becoming squared off at the corners instead of rounded. In most cases there is a collar of new bone at the margin of the articular surface right round the dorsal surface. Sometimes with or without this collar, definite large exostoses are formed, and occasionally these are attached by a narrow pedicle. The synovial membrane of the joint is thickened and sometimes becomes villous, sometimes there is cystic degeneration, so that around the joint a swelling may form looking like a ganglion and containing glairy synovial fluid. Very occasionally a loose body may be found in the joint.

In the early stages extension of the joint becomes limited, and later it is gradually abolished. In very severe cases the toe may become permanently flexed and incapable of extension even to the straight line position Pain is sometimes due to actual pressure upon the exostosis, over which a bursa may develop: very often it is due to the fact that the forcing of extension, which occurs at every step, is painful. The presence of any considerable mass of new bone on the outer side of the head of the first metatarsal in proximity to the second metatarsal is almost certain to be associated with severe pain.

Hallux rigidus often comes on in adolescence. although the more severe effects may only be evident many years later In unilateral cases there is often a history of injury to the toe, such as stubbing the toe severely, or tripping and forcing extension or flexion violently. Bilateral cases and cases in which there is no injury are common, and it is difficult to find a causative factor. Probably the wearing of shoes that have become too short, so that the toe is continuously pressed backwards, is an important cause, and any slight injuries to the toes during the period of growth are also important The teaching of toe dancing to children without suitable preparation is undoubtedly a factor in some cases.

Non-Operative Treatment.

In early cases of hallux valgus an effort should be made to prevent the progress of the deformity and to avoid the need for operative treatment. The longitudinal and transverse arches should be adequately supported. the former by thickening the inner side of the sole of the shoe slightly, the latter by strapping the foot circularly behind the heads of the metatarsals for a period of two or three months at a time. If the longitudinal arch is really flat, it may be necessary to lift it by inserting a pad in the shoe. but this should seldom be required if shoes are acurately fitted and the waist strengthened so that it does not give way. Defects in shoes such as those mentioned above should be avoided. Great care should be taken that shoes do not press upon the head of the metatarsal bone and cause additional inflammation. In young people much can be done by massage. first getting the big and second toes thoroughly mobile and then trying to re-educate in use the small muscles of the foot. Voluntary abduction of the big toe should be taught, also flexion of all the toes at the metatarsophalangeal joints, and the exercise of raising the transverse arch of the foot by pressing the toes against the ground should be practised.

in London where members could meet and where sanitary appliances could be submitted for inspection and experiment, to watch all measures introduced to Parliament relating to public health and to take action thereon if necessary, and to obtain a Charter for the purpose of examining and granting certificates of qualification to surveyors of sanitary districts and inspectors of nuisances The next step was taken at a public meeting in St James's Hall under the presidency of the sixth Duke of Northumberland, the Institute came into being and the Duke became its first President At the beginning, as usual, there were financial difficulties, for the new-born Institute had no backing from the Government or from existing institutions, but by 1877, in which year its first congress was held at Leamington under the presidency of Dr B W Richardson, the treasurer was able to show a credit balance of £32 10*s* 3*d* Dr. Richardson was a great asset to the Institute on account of his paper entitled Hygeia, the Ideal City of Health, read at the Social Science Congress at Brighton in 1875, which had established him in the eyes of the public as a leading medical light on the new science of preventive medicine, the subject aroused interest not only in England but also in France, owing to the brilliant sketch of the paper given by Jules Verne in his romance, "The Begum's Fortune" Dr Parkes supplies interesting biographical notes of the pioneers associated with the early days of the Institute, beginning with Edward Alexander Parkes, originator of the Parkes Museum of Hygiene, who was chief begetter of the Institute although he died before it came into being He gives a full description of the work of the Institute during the 50 years of its existence, ending his book with a series of admirable special articles on sanitary progress during the period under review

CAMBRIDGE MEDICAL SOCIETY IN AMERICA

SEVENTY-EIGHT members of the Cambridge University Medical Society have been visiting the United States and Canada during the past month and have returned full of enthusiasm at their reception All but two of the party were students or had lately qualified, and their object was to get an idea of the methods and ideals of American education by visiting universities and hospitals Nothing quite like this has been done before, and it is satisfactory that the experiment was a complete success Only 23 days were spent ashore, but an incredible amount was seen and done, thanks to the careful planning of details and the unfailing kindness of the Society's American hosts in every city The following places were visited Montreal (McGill University, Royal Victoria and General Hospitals), Kingston University; Toronto (University, Children's and General Hospitals, and the Insulin Building), Niagara, Washington (Hygienic Laboratory, Surgeon-General's Library, Walter Reed and Naval Hospitals), Baltimore (Johns Hopkins Hospital), Philadelphia (University of Pennsylvania Hospital), New York (Columbia University and new medical building, Rockefeller Foundation, Bellevue Hospital, and Cornell Medical School), New Haven (Yale University and General Hospital), and Boston (Harvard University, Peter Bent Brigham, Boston Lying-in, Children's, Psychopathic, City, and Massachusetts General Hospitals) Various methods of demonstration were adopted Sometimes special emphasis was laid on equipment and organisation; in New York it was possible to see a sky-scraper hospital and medical school actually in course of construction In other cases series of short clinical lectures, demonstrations, or surgical operations were utilised to illustrate the work being done in the hospitals or the method of teaching adopted It was always feasible for those specially interested in any particular branch of medicine to follow their own bent, and for the whole party to meet members of the faculties, who put themselves at their service—as one of the visitors expresses it—in a way that would have honoured far more distinguished guests Time was also found for sight-seeing, and there were social occasions described as peculiarly delightful Some appreciation of American and Canadian outlook and ideals must have been gained by everyone, and the experience will be of great value to each member of the party as an individual Since all of them are, or soon will be, spread about in hospitals and medical schools all over the country this experience may well have far-reaching effects At any rate, members of the Society have come home full of gratitude for the kindness and hospitality they have received and anxious to do anything they can for American and Canadian students, and especially for medical students visiting this country.

The Services.

ROYAL NAVAL MEDICAL SERVICE

Surg Comdr M J Laffan is placed on Retd List with the rank of Surg Capt

Surg Lt-Comdr P N Button to be Surg Comdr

The following appointments are notified —Surg Comdrs (D) J R Palmer to *Vivid* for R N Barracks, Devonport (on relief), and W C Murray to *Victory* for R N Barracks, Portsmouth (on relief) Surg Lt-Comdrs (D) W E A Sampson to *Vivid* for R N Hospital, Plymouth, and M F Hopson to *Pembroke* for R M Infirmary, Deal

ROYAL ARMY MEDICAL CORPS

Col C W Mainprise, late R A M C, to be Maj-Gen, vice Maj-Gen D J Collins, late R A M C, who retires on retd pay

Maj G E Cathcart to be Lt-Col, vice Lt-Col and Bt-Col H C R Hime (promoted)

The undermentioned are secd for service under the Foreign Office Maj and Bt Lt-Col H M J Perry and Capt H J Bensted Capt G S McConkey to be Maj (Prov)

The undermentioned Lts to be Capts F C H Sergeant and W L S Cox

J W de W G Thornton to be temp Lt

ARMY DENTAL CORPS

Temp Capt J McCurdy, Dental Surg, Gen List, to be Capt

ARMY RESERVE OF OFFICERS

The undermentioned having attained the age limit of liability to recall, cease to belong to the Res of Off Lt-Gen Sir C H Burtchaell and Col A G T Cusins

Maj L T Challenor, late R A M C, T A, to be Maj

TERRITORIAL ARMY

A A Allison to be Lt

ROYAL AIR FORCE

Flying Officer A Harvey is granted a permanent commission

J Hutchieson is granted a short service commission as a Flying Officer for three years on the active list

Flying Officer F P Schofield is promoted to the rank of Flight Lt

Flying Officer C J MacQuillan is transferred to the Reserve, Class D 2

It is officially announced that the King has approved of the appointment of Lt-Gen Sir Matthew H G Fell, K C B, C M G, late R A M C, to be Honorary Physician to his Majesty, with effect from June 3rd, vice Lt-Gen Sir William B Leishman, K C B, K C M G, F R S, late R A M C, deceased

ST BARTHOLOMEW'S HOSPITAL —In connexion with the Fleet-street Week for Bart.'s, an Empire concert is to be given in aid of the hospital, on Tuesday, Oct 12th, at 8 15 P M, at the Kingsway Hall, London Tickets may be had from the organisers at 3, Red Lion-court, Fleet-street, E C 4

PROF DR. FRANS DAELS AND DR G BACTEN · MALIGNANT TUMOURS EXPERIMENTALLY OBTAINED BY MEANS OF RADIUM

In hallux rigidus seen in the fairly acute stage in young people complete rest of the foot for several weeks should first be ordered Shoes should then be carefully fitted with the inner side of the heel thickened and a patch put on to the sole behind the head of the first metatarsal in order to lift the big toe from the ground and throw the weight on to the outer border of the foot The soles should be thick, and the uppers free from stitching in the region of the metatarso-phalangeal joint of the big toe With rest, followed by careful attention to shoes, many of the more acute cases in young people will clear up completely and leave no after effects In older people in whom hallux rigidus is already established similar attention to shoes will often relieve symptoms and avoid the need for operation

Operative Treatment.

Many operations have been tried for hallux valgus, but only two have stood the test of time These are (1) excision of the head of the metatarsal, (2) removal of the inner half of the head of the metatarsal (so-called removal of the exostosis) In most cases complete excision gives the best result By this means the deformity can be corrected, the prominent bone removed and the symptoms relieved, whatever their cause By removal of the exostosis alone, symptoms due to pressure upon it and upon the bursa overlying it are relieved, at any rate, for a considerable period, but the toe is not straightened even when the external lateral ligament of the joint is divided and thus interference with the use of the second and other toes continues

The operation of excision is a small one, but it requires to be carefully carried out It is best done by a dorsal incision, the joint being opened by a transverse incision, leaving a part of the capsule attached to the first phalanx. The head is freed from its lateral ligaments and is then carefully re-shaped with a fine osteotome and rounded off A small portion of the head on the under surface can usually be left so as to form a bearing surface upon which the patient walks The cut surface of bone is finally filed down smoothly and may be covered by rubbing with Horsley's wax Some operators cover the exposed bone with a flap of fascia or a flap taken from the deep part of the bursa The capsule is sutured over the bone before the skin is sutured

In the exostosis operation a similar exposure is necessary The projecting part of the inner side of the head is removed and the lateral ligament on the outer side of the joint divided Patients may be allowed to walk 10 to 12 days after either of these operations, after-treatment should include (1) strapping the toe in the corrected position and placing straps circularly around the heads of the metatarsals for a period of two months, and (2) massage, mobilisation of the four outer toes, and exercises for flexion of these toes and for re-education in a proper method of walking

In hallux rigidus it is necessary to analyse the exact cause of the disability Sometimes there is one local exostosis which is painful, because exposed to pressure upon it, it is then only necessary to remove this exostosis More often there is extensive overgrowth of bone around the head of the metatarsal, and extension of the joint is painful In these cases it is necessary to do a more extensive operation, usually one similar to that done for hallux valgus, the head of the bone being exposed, carefully trimmed down, and a new head formed Occasionally a simple removal of all the osteophytes around the head may be carried out and the actual cartilage covering the extremity left intact This, however, does not suffice for cases where the pain is due to extension movement of the joint The after-treatment for hallux rigidus is exactly the same as that for hallux valgus

In cases where the bursa overlying the joint has suppurated and is discharging at the time of operation, it is necessary as a rule to do a limited operation first, excising the bursa and thus getting rid of the suppuration, later on the excision operation may be carried out.

A NOTE ON THE DIFFERENT KINDS OF MALIGNANT TUMOURS EXPERIMENTALLY OBTAINED BY MEANS OF RADIUM

By PROF DR FRANS DAELS
AND
DR G BACTEN,
ASSISTANT

(*From the Cancer Research Centre, Ghent*)

It is of paramount significance that we are able to produce experimentally malignant growths by means of a well-defined agent, which is easy to study in its effects It enables us better to observe the genesis of the tumours, we have their formation under more direct control, and we shall in future be able to tackle the question of vaccination in a more methodical manner with autochthonous tumours A well-known, easily analysed, cancer-producing agent would afford us a better opportunity of producing malignant growths in laboratory animals which are easier to treat than mice and rats Arising out of these considerations efforts have been made for several years at the laboratory of the Gynæcological Clinic of Ghent University to produce malignant new growths by means of radium—viz, as a mixture of radium with paraffin or talc powder and also in aqueous solutions of radium

So far we have thus been able to obtain the formation of a sarcoma in white rats and white mice and of an epithelioma in a white mouse

The first histological type obtained was a spindle celled sarcoma At the London Congress of Radiology in 1925 one of us had the opportunity of making a statement on the subject, when it appeared that it was also the first contribution to scientific literature on the undoubted experimental production of malignant new growths by means of radium

A spindle-celled sarcoma, showing irregular nuclei of very unequal size, also some giant nuclei and a few lymphocytes (Fig 1), appeared in a white rat 392 days after subcutaneous insertion of a glass tube containing 50 mg of radium powder—i e, a mixture of *10 g* talc with 1 mg radium sulphate

A spindle-celled sarcoma consisting of typical parts and also of a considerable amount of necrotic tissue with thrombosed vessels and giant nuclei (Fig 2) was found in a white rat in whom a glass tube containing a few drops of radium solution (*5 mg* crystallised radium bromide in 100 c cm distilled water) had been retained for seven months in the subcutaneous connective tissue

A sarcoma chiefly made of cells obviously partly necrosed with small nuclei and remnants of nuclei after karyorrhexis or partial karyolysis and a few larger nuclei (Fig 3) was obtained in a mouse which retained under the skin for a period of eight months a solution of 1/20,000 crystallised radium bromide in a small tube

A spindle-celled sarcoma with marked lymphocytic infiltration (Fig 4) appeared in a mouse in which a tube with 1/10,000 radium bromide solution remained in the subcutaneous connective tissue during eight months

In a third mouse, which retained in the subcutaneous tissue for a period of eight and a half months a tube with a similar (1/10,000) radium bromide solution, a typical spindle-celled sarcoma was produced without any infiltration of extraneous elements (Fig 5)

A cancroidal epithelioma (Fig 6) was obtained in a mouse in which a tube holding a few drops of a radium solution of 10 mg radium bromide in 100 c cm water was inserted under the skin and retained for 322 days

In this case metastases appeared at the level of the right axilla and the left groin.

The initial or early stages of the epitheliomatous degeneration as seen in our sections show the same epithelial hyperplasia and hypertrophy as are found in other cases.

The first stages of sarcomatous degeneration chiefly consist of degeneration of the endothelial nuclei.

AN INQUIRY INTO RHEUMATISM IN ELEMENTARY SCHOOL-CHILDREN.

BY RICHARD H. VERCOE, B.A. CAMB., M.R.C.S. ENG., D.P.H. OXF.,
MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER, BOROUGH OF CHELMSFORD.

THE principal object of this investigation was to estimate the relative importance of rheumatism in the parents and of dampness in the home respectively in their effect (if any) on rheumatism in the child. Other factors, such as teeth, tonsils, scarlet fever, and nutrition, have also been tabulated.

Definition of Terms.

Such indications of rheumatism as rheumatic nodules or heart disease have not been adopted as criteria. Neither is available for estimating parental rheumatism, and the findings of the former vary from 10 to 40 per cent. with different observers. The criterion adopted has been the symptoms of the child as related by the mother and corroborated by the child, if old enough. Rheumatic fever is recorded if the child has had pain with swelling or redness in any joint increased by movement, combined with fever and confinement to bed. In some cases further confirmation is forthcoming from the reported diagnosis of the doctor in attendance at the time, or from striking speedy relief of pain soon after taking the medicine (presumably salicylate), or from evidence of heart disease following such joint symptoms. Subacute rheumatic fever was recorded when the child has had swollen painful joints, with some one or other of the above symptoms, but not confined to bed. In the following figures subacute rheumatic fever has been included among the rheumatic fever cases. Definite rheumatism was recorded if the child had had definite pains on several occasions in one or more joints, or persistently in the limbs on several occasions without ever being confined to bed and without fever or joint swelling or redness. Slight rheumatism was recorded when the pains were infrequent and mild, but occurred on more than one occasion; anything less than this was put into the non-rheumatic group which was used as a control throughout.

System of Collecting Data.

At the school routine medical examination the child was first medically examined in the usual way; secondly the mother was questioned as to rheumatism in the child and in the mother and father, then as to dampness in the home; and thirdly, the history was taken of past infectious disease in the child. In this way the first interpretations of the physical signs were not prejudiced by the history of the symptoms, and any objection by the parent to inquiry into parental symptoms was mitigated by sandwiching the personal questions between the examination of the child and its history of past infections.

Only those cases were recorded as routine rheumatic and non-rheumatic cases when I had arranged at the beginning of the examination to inquire from every parent who was present at that session into the history of rheumatism and dampness. It is only in this way that any estimate could be formed of the amount of rheumatism, as the negative cases were then recorded in the same relative proportion as the positive. If a parent volunteered the information that her child had had rheumatism in the course of a session, when for pressure of time I was not inquiring into rheumatism, then such a case was put into the group of rheumatic "specials," and utilised in tables which would not be vitiated by this method of collection. A child was classed as rheumatic, both if it had actual rheumatism at the time of the examination, and also if it had had definite attacks in the past.

Dampness in the home was recorded if the bedrooms or living room were said to be really damp, not if some less used room only was involved. The sanitary inspector looked over the whole of the addresses afterwards with me at my request and the final verdict was determined by his intimate knowledge of the houses extending over 14 years, and to him I am indebted for these estimations. Some houses were hardly really damp but more damp than dry and were then recorded by us as slightly damp. Dampness of the site apart from the house was also estimated with the inspector's help, the parent here not being asked, and was recorded separately. These terms are rather loose and difficult to define, but the personal equation is uniform for the series.

Age and Sex Distribution.

The routine inquiry into rheumatism was made on a total of 702 children of both sexes, aged 5, 8, 11, 12. Of these 702 children 99 had had rheumatism in some form or another, while 603 had not had rheumatism in any form. Table I. sets out the number and relative proportions of rheumatic and non-rheumatic children in each separate age-group and sex.

TABLE I.—*Age and Sex Distribution.*

Rh. = rheumatic.

—	Aged 5			Aged 8.			Aged 11.			Aged 12.		
	Girls.	Boys.	Total.	Girls.	Boys.	Total.	Girls.	Boys.	Total.	Girls.	Boys.	Total.
Rh.	6	4	10	15	18	33	4	7	11	21	24	45
Non-rh.	52	68	120	113	162	275	16	22	38	92	78	170
%	11.5	5.9	8.3	13.3	11.1	12.0	—	—	—	22.8	31.8	26.4

It will be seen that the amount of rheumatism rises steadily with increase of age (omitting the 11-year-olds, which are small in number), and is three times as much at 12 as at 5 years old. Rheumatism actually appears a little less prevalent among the parents than among the 12-year-olds, which may be explained either by defective memory or because the infection of rheumatism has already mainly occurred by the age of 12.

Adding together the figures for all three age-groups the girls show an average percentage of 15.87, the boys of 15.93, as nearly equal as is well possible.

Subdividing the rheumatic cases into clinical categories—

	Rh. fever.	Definite rh.	Slight rh.	Total.
Girls	9	33	4	46
Boys	9	28	16	53

Of cardiac complications there were 4 cases of mitral regurgitation among 18 routine cases of rheumatic fever, 3 cases among 81 routine cases of remaining rheumatism and 3 cases among 603 routine non-rheumatic cases

It does not seem that rheumatism is necessarily any more frequent in the slummy home than in the good one amongst elementary school-children.

TABLE III.

—	Totals recorded.				Percentages.			
	Good.	Av.	Bad.	Poor.	Good.	Av.	Bad.	Poor.
5's	12	[illegible]	6	2	[illegible]	[illegible]	[illegible]	[illegible]
12's ..	47	[illegible]	77	13	[illegible]	[illegible]	[illegible]	[illegible]

Av. = Average.

Conclusion.

The four factors—parental history, dampness, teeth, tonsils—can be compared in the following table of percentages (Table IV.):—

TABLE IV.

Children.	Rheumatic parents.	Dampness.		Septic teeth.		Tonsils.	
		House.	Site.	Cases.	Per cent.	Enl.	Rem.
5's	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
12's ..	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]

Enl. = enlarged. Rem. = removed.

From Table IV. it can be seen at a glance not only which is the most important factor of these four, but also what is its approximate mathematical relationship to its own importance and to that of the others. Parental history seems much the most important association. Dampness of the house is next; while teeth have no association, unless it be in some rare and exceptional instance. Tonsils must be judged by the amount of sepsis that may have been involved in their removal. There appears to be no association with scarlet fever, poor home conditions, malnutrition, or sex. Age shows a very definite association, the 12-year-olds having three times as many cases of rheumatism as the 5's, probably because there has been much longer time to acquire the infection or to feel its effects.

SURGICAL TREATMENT OF CANCER OF THE BREAST.

REVISED MEMORANDUM OF DEPARTMENTAL COMMITTEE OF MINISTRY OF HEALTH.

THE fifth[1] of the series of reviews summarising the position of modern knowledge and practice in regard to different aspects of cancer, now being issued by the Departmental Committee on Cancer of the Ministry of Health, supplements information already given in the third memorandum[2] of the series by incorporating the additional and more exact data which the Committee have since obtained. On an examination of the literature of the subject, the Departmental Committee felt justified in 1924 in directing public attention to the danger of delay in obtaining early diagnosis and early surgical treatment of this form of cancer, and in insisting that patients undergoing the complete operation for cancer of the breast at an early stage, before the disease had spread from the breast, were assured of a highly favourable prognosis. These conclusions have since been put to the practical test of special follow-up inquiries by the medical officers of health of London, Manchester, Liverpool, Birmingham, Sheffield and other large cities, which have demonstrated that the results secured by complete operation at an early stage are even better, in terms of length of subsequent healthy life, than had been demonstrated by the literature. Collateral inquiries have brought to light other facts of importance in cancer of the breast, particularly its association with certain antecedent conditions and its duration under circumstances when, for one reason or another, no attempt to obtain a radical cure was practicable.

Natural Course of Untreated Cancer.

The results of the new inquiries enable the Cancer Committee to express the natural course of untreated cancer of the breast and the antecedent circumstances associated with its origin. Cancer of the breast constitutes the largest portion of cancer mortality contributed by a single organ amongst women in England and Wales, and after the age of 45 it is a very serious factor in the total mortality. In its early stages, it is emphasised once again, cancer is usually unattended by pain. For many reasons the natural duration of cancer of the breast is difficult to state with precision. Thus (1) the onset frequently cannot be fixed with any degree of accuracy; (2) amongst cases of cancer, even in women of the same age and of the same habit of body, some run an acute, others a chronic, course; and (3) the age at which the patient becomes affected appears to exert an influence upon the natural course of the disease—cancer probably takes, on the whole, a more rapid course in the young person than in the old. It should also be added that if cancer of the breast supervene during pregnancy or lactation, the course of the disease may be abnormally rapid. Although for these reasons it cannot be stated precisely, the average natural duration of a case of cancer of the breast appears to be a little over three years, as is set out more fully in Dr. M. Greenwood's report which appeared last July.[3]

Recent investigations by Dr. Janet Lane-Claypon have demonstrated statistically[4] that both chronic mastitis and a history of injury are of more common occurrence in women who subsequently develop cancer of the breast than in those remaining unaffected. It is the less fertile married women and those whose histories disclose the previous occurrence of other events and conditions such as acute transient mastitis, deformity or abnormality of the breast, and perhaps also one of excessive prolongation of suckling, who are more prone to suffer from the disease. On the other hand, certain events in the life history of women—such as the period of onset, duration, and time of cessation of menstruation, disturbances connected with that function and the [illegible] nature of [illegible], &c., some of which have been supposed to exert an influence in causation—were shown to be no more significant in women who afterwards suffered from cancer of the breast than in those who did not. This knowledge may open up a wide field of investigation whereby the development of a cancer may be traced back to its starting-point, which [illegible] by a [illegible] of some pre-existing condition of disease on which it [illegible] to some definite change in the character of growth of cells which have hitherto behaved in a normal fashion.

Diagnosis and Early Treatment.

The difficulty in identifying the nature of a mass in the breast of a woman of middle or late age is frankly admitted. When the cancer is fully developed, especially if accompanied by enlargement of lymphatic glands in the axilla, the diagnosis can readily be made with a high degree of certainty. [illegible]

[2] THE LANCET, 1924, ii., [illegible]

[3] [illegible]

[4] [illegible]

Comparison of Ætiological Factors

As the 5-year-old group only contains 10 cases of rheumatism and such an age is useless for estimating effect of teeth, tonsils, scarlet fever and even perhaps dampness, this group is discarded hereafter. On the other hand, 16 specials, at ages 8 and 12, are utilised separately below in order to increase the rheumatic group and bring its numbers nearer the non-rheumatic Thus there is now a total of 105 rheumatic children The average age of all the rheumatic children is practically the same (10 2) as that of the non-rheumatic (10 1)

Parental Rheumatism —89 routine rheumatic children have 178 parents, of whom 73 have had rheumatism—i e , 41 0 per cent ; 483 routine non-rheumatic children have 966 parents, of whom 163 have had rheumatism—i e , 15 8 per cent (If we add in 16 special rheumatic children we find there are 14 extra rheumatic parents out of 32 parents and the total percentage is then 41 4 for all the rheumatic children) Analysis of the parental rheumatism is as follows .—

Rheumatic parents of—	Rh fever	Definite rh	Slight rh	Total.
Rheumatic children	7	62	18	87
Non-rheumatic children	13	132	18	163

So that the proportion of parents who have had rheumatic fever and definite rheumatism is approximately the same in both the rheumatic and non-rheumatic groups It might be argued that the apparent influence of the parental rheumatism might really be due to the dampness of the house and vice versa in so far as the rheumatism of the parent might be caused by the dampness of the house in which the child also lives The cases where these coincide were therefore tabulated as follows :—

Rheumatic parents of—	Living in— Dry houses	Rather damp	Damp	Total.
Rheumatic children	67	6	14	87
Non-rheumatic children	132	17	14	163

So that the proportion of rheumatic parents living in dry houses is approximately equal in both groups of children, the rheumatic and non-rheumatic, and even supposing the parents had been living in these houses for as relatively long a time as the children, yet there seems nothing to suggest that this can much modify the great difference of 41 per cent and 16 per cent for rheumatic and non-rheumatic children, respectively, as regards their family history So that the rheumatic children have very nearly three times as many rheumatic parents as the non-rheumatic children

Dampness —The way in which dampness of the house was assessed has already been described Of the rheumatic children, 27 houses were damp out of 105 (i e , 25 9 per cent) Of the non-rheumatic children, 69 houses were damp out of 483 (i e , 14 3 per cent) So that the percentage of damp houses was nearly twice as great among rheumatic children as among the non-rheumatic In regard to dampness of the site on which the house was built, only the 11- and 12-year-old children were inquired into, the condition of the site being recorded quite independently of that of the house which was not taken any notice of in the following results · Of the rheumatic children, the site was damp in 14 out of 45 (i e , 31 per cent) Of the non-rheumatic children, the site was damp in 61 out of 162 (i e , 37 per cent) So that dampness of the site considered by itself seems to have no effect, that is as regards the local sites here considered, the dampness of which was never extremely pronounced

Teeth —Only the septic teeth were counted, those showing only a small spot to be filled were omitted as unlikely to have any appreciable effect in producing rheumatism Of the rheumatic children, 15 out of 105 had septic teeth (i e , 14 3 per cent) Of the non-rheumatic children, 65 out of 483 had septic teeth (i e , 13 1 per cent) The average number of septic teeth per case with septic teeth was rheumatic 2 0, non-rheumatic 2 3 So that the condition of the teeth does not appear to have any effect in producing rheumatism in the vast majority of rheumatic children of elementary school age, whatever may be its effect on adults It should be remembered that there must be a very great difference between children aged 12 (still more aged 8) and middle-aged adults with regard to the length of time the bad teeth are present, and the extent and depth of the sepsis

Tonsils —The cases where the tonsils were septic as well as enlarged were too few to form any comparison, but those which had been removed by operation would include many of these, and after some hesitation I decided not to ignore those operated upon, but to record them separately from those which were enlarged The result is tabulated as follows —

Tonsils of—	Enlarged.	Removed.
105 rheumatic children	10 = 9 5 %	12 = 11 4 %
483 non-rheumatic children	51 = 10 6 %	29 = 6 2 %

So that enlargement of the tonsils was a little less in the rheumatic than in the non-rheumatic, while cases where the tonsils had been removed, perhaps only because the adenoids were being removed, were nearly twice as frequent in those who had had rheumatism as in those who had never had rheumatism

Scarlet Fever —In 105 rheumatic cases there were 4 who had had scarlet fever (i e , 3 8 per cent) In 483 non-rheumatic cases there were 15 who had had scarlet fever (i e , 3·1 per cent) So that the association between rheumatism and scarlet fever appears to be negligible, so far as concerns the small number of cases in this series

Comparison of Physique and Home Conditions

The average height and weight of girls and boys, aged 8 and 12, is compared in Table II and affords some indication whether *malnutrition* is associated with rheumatism or not It will be noticed that the number of rheumatic children is a little larger than in the first table by reason of inclusion of some specials (for rheumatism) with the original routines

TABLE II —*Physique*

—	Girls				Boys				Combined sexes		
	No	Age	Height	Weight	No	Age.	Height	Weight	Age	Height	Weight
			in	lb			in	lb		in	lb
Rh	26	$12^{3}/_{12}$	56 8	77 7	25	$12^{3}/_{12}$	55 4	74 2	$12^{3}/_{12}$	56 1	75 9
Non-rh	92	$12^{4}/_{12}$	56 2	74 0	78	$12^{3}/_{12}$	55 6	76 6	$12^{3}/_{12}$	55 9	75 3
Rh	19	$8^{4}/_{12}$	47 6	50 2	20	$8^{4}/_{12}$	45 6	52 8	$8^{5}/_{1}$	46 3	51 5
Non-rh	113	$8^{3}/_{12}$	46 7	51 7	148	$8^{4}/_{12}$	48 9	54 6	$8^{4}/_{12}$	47 8	53 1

As the ages of the groups of children are almost exactly equal to a month in all the groups compared there is no correction necessary for the factor of age The average height and weight of the 12-year-olds, combining the average in girls and boys, appears practically equal in both the rheumatic and non-rheumatic groups, but is very slightly less in the non-rheumatic In the 8-year-olds, on the other hand, the rheumatic group is distinctly the shorter and lighter by 1½ in and 1½ lb However, in both the 8-year and the 12-year group the difference between rheumatic and non-rheumatic appears too small to be of much significance, and in both cases the former are fully up to the average height and weight for the age Nutrition, therefore, does not seem definitely to be a factor influencing the incidence of rheumatism

The character of *home conditions*—good, average, fair, poor—was also investigated The school nurse briefly recorded her opinion opposite each name and address which she knew, as far as her intimate knowledge of the families permits, which is very considerable and extends over several years The result was then tabulated (Table III)

COOMBE HOSPITAL CENTENARY.

CONGRESS AT DUBLIN.

We published last week (The Lancet, Sept. 18th, p. 614) a short account of the Coombe Hospital, which celebrated its centenary by a Congress at Dublin from Sept. 14th to 17th. Amongst gynæcologists who attended from various parts of the world were Prof. J. P. Faure and Prof. A. Couvelaire, of Paris and many others whose names appear below.

After a brief presidential address from Sir William Smyly (Dublin), the proceedings opened with a paper by Prof. Essen Möller (Lund) on the

Teaching of Obstetrics.

He described the teaching of obstetrics in Swedish universities, where the medical course, he said, was from eight to nine years. Of this time the student spent four months in intensive study of obstetrics and gynæcology as an intern, the obstetric and gynæcological hospital being in each case under the control of the university professor.

Prof. Munro Kerr (Glasgow) pleaded for a simplification of obstetric teaching, and urged that three months training was adequate to make the student a safe obstetrician. He also emphasised the importance of antenatal work.

Prof. J. B. de Lee (Chicago) describing the course of study in Chicago, stated that two of the student's last four years were given to obstetrics, of which (apparently) only two or three weeks were given to clinical work. The student would see from 8 to 20 normal deliveries and a few forceps cases.

Mr J. S Fairbairn (London) said that at St. Thomas's Hospital six months were given to obstetrics and pædiatrics, two months being spent in residence. The student saw the patients in the antenatal clinic, in the indoor department, and in the postnatal clinic

Prof. Fletcher Shaw (Manchester) said that in Manchester a year was spent in theoretical teaching of obstetrics, and five months in clinical work, of which one month was in hospital. No attempt should be made to teach students to become operating obstetricians.

Mr Comyns Berkeley (London) described at length the difficulties experienced by obstetric teachers in urging the General Medical Council to maintain an adequate standard in the teaching of midwifery. In his opinion the number of obstetricians on the Council should be increased

Mr Eardley Holland (London) read a paper on the

Unnecessary Induction of Labour.

He believed that induction of labour for contracted pelvis and for so-called prolongation of pregnancy was being greatly overdone. An excellent criterion of the necessity or otherwise of induction in any given case of contracted pelvis was the length of the second stage of labour. In a series of 123 cases at the City of London Maternity Hospital the length of this stage had been less than one hour—in many cases only a few minutes—in 63 per cent., and between one and two hours in 22 per cent. of the remainder. In these cases clearly the induction had not been necessary and the patients could have delivered themselves spontaneously at full term. It was well known that spontaneous delivery occurred in about 80 per cent of cases of moderate pelvic contraction As regards so-called prolongation of pregnancy, it had been the custom of the Hospital to induce labour after the prescribed term of 280 days had been exceeded by a week or ten days An analysis of the records of 82 cases of this nature had demonstrated that induction had been unnecessary in nearly all Calculation from the date of the last menstrual flow gave an error of roughly three weeks

Subjects under Discussion

Other papers read before the Congress included one by Prof Paul Werner (Vienna) in which he gave his results in the treatment of pre-climacteric and climacteric bleedings by irradiation. A paper by Prof. Munro Kerr, stating the case for the lower uterine segment Cæsarean operation gave rise to an interesting discussion.

Prof. A. Donald (Manchester) read a note dealing with the history of antisepsis and asepsis in midwifery. He regarded corrosive sublimate as the most useful antiseptic for disinfection of the hands and external genitals Gloves, he thought, gave a false sense of security, and he urged the simplification of the antiseptic ritual in the homes of the poor, concluding with a cogent criticism of the theory of endogenous infection.

Prof. de Lee read a somewhat provocative paper entitled the Pathogenicity of Parturition, in support of his thesis "that the function of child-bearing, while it may have been intended by Nature at the beginning to be a normal, harmless process, has in the modern, civilised woman acquired qualities which stamp it as pathologic."

Prof. Louise McIlroy (London) discussed Some Problems of Diagnosis and Prognosis in Antenatal Work, with particular reference to the association of clinical and X ray examination of the pregnant woman.

Prof H. Hinselmann (Altona), opening a discussion on eclampsia argued that clinically eclampsia was due to a profoundly altered peripheral circulation of the nature of angiospasm. The brain, he said, was the last organ to be affected, while mortality was due to the condition of the heart.—Dr. J. Hendry stated that of a recent series of 23 fatal cases of eclampsia the cause of death in 11 was pulmonary œdema. In a series of 100 cases recently treated by conservative methods in the Royal Maternity Hospital, Glasgow, the number of deaths was 10—Dr. Gibbon Fitz-Gibbon (Dublin) laid stress on the value of early prenatal care in the prevention of eclampsia

The closing paper of the Congress was an essay by Prof. Beckwith Whitehouse (Birmingham) entitled a Contribution to the Pathology and Causation of Dysmenorrhœa. He distinguished what he called "aconceptional dysmenorrhœa" from menorrhagia, and believed that the former was always associated with the expulsion of tissues from the uterine cavity, while the degree of pain was dependent on the degree of denudation of the endometrium. The tissue expelled consisted usually of hyperplastic decidua the hyperplasia probably being due to excessive lutein activity.

Social Functions of Congress.

The opening ceremony of the celebration of the Hospital's centenary was held on Sept 14th when there was a reception by the guardians and directors of the Hospital at the Royal College of Surgeons The various British and foreign guests were present, together with representatives of the medical and other professions in Ireland. A welcome to the guests was given by the President of the Royal College of Surgeons and by the Chairman of the Board of Governors of the Coombe Hospital

On the following evening a dinner to the visitors and to the friends of the Hospital was given in the Hall of the Royal College of Surgeons by Alderman Hubbard Clark, Chairman of the Board of Governors of the Hospital, and Mrs Clark. About 160 people were present The toast of the Coombe Hospital was proposed by Prof Munro Kerr and a reply was given by Dr Louis Cassidy, the Master Among the other speakers were Mr A. Fullerton (President of the Royal College of Surgeons in Ireland), Rev. T. A. Finlay, S J., Mr. W. Doolin, Mr Comyns Berkeley, Prof Faure, and Prof. Werner.

On the evening of Sept 16th a special performance was given at the Abbey Theatre of Mr Sean O Casey's play "Juno and the Paycock. Mr W B Yeats one of the directors of the theatre appeared before the curtain after the first act and welcomed the guests on behalf of the directors and players of the Abbey of cancer cells Examination of microscopical sections during the course of operation has not proved satisfactory since masses which are difficult to identify with the naked eye are very frequently those which display doubtful appearances when examined by the rapid method of making microscopical sections, used in the course of an operation The method which combines the greatest reliability with the least risk is that of incision into the growth at the time of operation, the surgeon being guided as to subsequent procedure by the naked-eye appearance of the incised tumour and employing the fullest precautions, change of gloves, instruments, &c , to avoid transference of cancer cells to the wound In early cases, the report concludes, the microscope is of little value in diagnosis prior to completion of the operation, it is of value in confirming the clinical diagnosis made by the surgeon prior to and during operation

Early surgical operation, the memorandum again states, affords the one chance for a patient suffering from cancer of the breast Cases of cancer treated only with internal medicines, or external applications, or by dietetic methods are not being effectually treated This does not mean that such agents as radium and X rays cannot be usefully employed as aids to surgery, or in cases in which surgical operation is impossible Decisions on the treatment depend on the primary question of the need for operation from the standpoint of the surgeon and of the patient The surgeon has to consider (*a*) whether the condition is actually cancerous or threatens to become so, (*b*) whether he can remove the disease completely without undue risk to the patient, and (*c*) whether the patient will be freed from the disease by the operation, or, alternatively, what will be the relief and the prolongation of life afforded by it The patient's standpoint is different She views the entire operation (including the anæsthetic) with repugnance and as a proceeding which, even if completely successful in a surgical sense, is an evil of no little magnitude Hence it comes about that with all the improvement in surgical technique there has been no corresponding increase in the proportion of cases which reach the surgeon at a stage of the disease when such treatment offers the greatest advantage Investigation has shown that on the average patients do not seek medical advice until eight or ten months after the growth was first noticed

As to varieties of operation, though full weight must be given to general improvements in surgical technique, it is regarded as indubitable that the better results obtained at the present time by operation in cancer of the breast depend upon the completeness with which the outlying portions of the cancer are removed No means exist for recognising at the time of operation the position of these outlying foci, and hence arises the necessity for the "complete" operation The extent of the operation has increased with fuller knowledge of the natural course of the disease, so that anything but a wide operation involving skin and deep fascia with complete removal of the breast, pectoral muscles, and axillary contents is almost universally recognised to be relatively, if not entirely, useless This complete operation does not add in any significant degree to the risk of the operation itself or to subsequent disability

Results of Operation

The memorandum as revised still regards as the most important point to determine the measure of success of surgical treatment The *average* duration of life in untreated patients (little more than three years) has been obtained by noting the duration of life in a large number of women whose history is known from the time when the tumour was first noticed until death No precisely comparable figure for patients who have been operated upon can be given Some patients—and under favourable conditions a large number of them—live for many years, and it is difficult for the surgeon to keep in touch with them for 10–15 or more years after operation A majority of surgeons have been content themselves with reporting percentages of survivals three years from operation The most recent investigation [5] of patients suffering from undoubted cancer of the breast, confirmed by microscopical examination, shows that, with the modern complete operation, 52 per cent are alive and well after a three-years' interval, 39 per cent after five years, and 30 per cent after ten years But some of these patients were already in a condition that the surgeon could have little confidence that the disease would not recur When the results were examined according to the *stage* the disease had reached at the time of operation, it was found that of patients subjected to early operation—i e, before the disease had extended beyond the breast itself—94 per cent were alive and well at the end of three years, 91 per cent at the end of five years, and 87 per cent at the end of ten years Figures for patients operated upon at later stages vary with the degree of advance of the disease and range from 31 to 38 per cent at three years, 15 to 20 per cent at five years, and 5 to 6 per cent at ten years Put in another way, it may be said that, on the average, women affected by cancer of the breast have, in the absence of effective treatment, roughly one-sixth of the normal duration of life to look forward to, those subjected to the complete operation during the comparatively late stage of the disease at which the average patient applies for treatment under present unsatisfactory conditions have about one-third of the normal duration to expect, while those so operated upon at an early stage may anticipate approximately two-thirds of the normal after-life time

Practical Applications

About 1 in 4 of all patients undergoing operation in large hospitals does so at a stage early enough to secure a good chance of cure In the case of the other three, application for treatment is delayed, largely through ignorance or fear, to such a late stage of the disease that the chances of complete relief are very considerably diminished The proportion of the total number of sufferers which undergoes operation in large hospitals is not precisely known, though it is probably in the region of 50 per cent What is the fate of the remaining 50 per cent ? Some undergo operation elsewhere—e g, in their own homes, nursing homes, cottage hospitals, &c —others attend hospital but at a stage too late to admit of any attempt at a radical cure, and it is probable that a third fraction either fall into the hands of unqualified practitioners of one kind or another, or come under the care of registered medical men only at the latest stage It may safely be stated that not more than 1 in 5 or 6 of all victims of this disease obtains the best treatment at her command

It is highly desirable that every possible means should be taken to try to induce all middle-aged women who are conscious of any abnormal condition in the breast to seek medical advice without delay The memorandum proposes that this should be attempted by dissemination of information through all suitable channels, such as leaflets, "talks," advice by local cancer committees, doctors, health visitors, and social workers, and in other ways Educative advice directed towards securing effective treatment of those earlier conditions which have been shown commonly to precede cancer and to the avoidance so far as possible of injury, especially habitual injury, would also be of value

Intensive efforts on a wide scale are now being devoted to the search for the cause or causes of malignant disease, but the memorandum sounds a note of caution, that the discovery of a cause may not necessarily indicate a means of prevention, and even though it did, preventive measures could not be expected to secure early results in cancer, since the bulk of the evidence indicates that the disease is one of slow development due to effective or predisposing causes operating over a prolonged period

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Responsibility for Venereal Infection

A CASE recently heard before the courts raised some interesting legal questions. The defendant was an officer in the army: in 1915 he made the acquaintance of the plaintiff who was then a girl of 15, employed as bookkeeper by a large private firm, and sexual relations began between them, which went on at intervals for many years, the officer always promising marriage at the end of the war. Whilst on service he contracted syphilis and on his return infected his fiancée, but their relations continued until two years ago, when the man refused marriage. At this the girl took legal action, demanding compensation for the damage done to her health and for the loss she had suffered in not being able to attend to her regular work: but the county court refused countenance to her claims on the ground that every love-relation arises from the common resolution of two persons, and therefore any damage arising from it must be borne in common. The plaintiff then appealed to the High Court, which has annulled the decision and has ordered an inquiry into the moral life of the girl before she got to know the defendant and has asked for a certificate stating that the captain has in fact suffered from venereal disease. The view of the High Court is that if the officer was responsible for the infection he should pay compensation not only for the cost of medical treatment, but also for any other pecuniary damage or loss of profit. The sentence of the county court, it is suggested, would actually reward the man for his immoral conduct.

An International University at Davos

Dr Eugen Kollarits, lecturer in the University of Budapest, who is at present living in Switzerland, has put forward an interesting plan for an international university at Davos. His idea is that the professorial staff, as well as the students, should be recruited from the citizens of all civilised nations, and this, he hopes, would do something to bridge the international gulfs left by the war. At the high altitude of Davos students in the early stage of pulmonary tuberculosis could go on with their work under favourable conditions and in healthy surroundings, far away from the dusty air of the big cities where universities are generally situated. There would be admirable facilities for sport, and Davos, which has a resident population of 10,000, seems to be an excellent place at which to set up such a university. Dr Kollarits suggests that the League of Nations should undertake its foundation; the 30 or more countries which are members of the League could contribute to the cost without any great effort.

Inoculation against Measles.

The Mayor of Budapest has issued an order dealing with the collection of serum from patients convalescent from measles. The order requires that hospitals which accommodate such patients, and also private practitioners, shall take blood from children over 4 years of age who show no signs of tubercle or syphilis. The blood is to be collected between the seventh and ninth days after the fever has subsided, and will at once be sent to the city's public laboratories where every specimen will be tested by the Wassermann reaction regardless of its origin. Half the serum thus collected will be placed at the disposal of practitioners for the prophylactic inoculation of families in which a case of measles has occurred. At present so little blood is available that the laboratories can only give small lots of tested serum to those doctors who have themselves contributed to the stock. Before taking blood or giving preventive inoculations the consent of the children's parents has to be obtained.

Prophylaxis and Treatment of Scarlet Fever.

Prof. Kornél Preisich [illegible] an address to [illegible] Medical Society [illegible] that, in his [illegible] primary negative Dick test does not mean unconditional immunity; he has seen the occurrence of scarlet fever shortly after a primary negative Dick test, and also in a child who had been immunised but was not quite Dick-negative. In many cases, he points out, it is exceedingly difficult to make the reaction negative, and it is more difficult to do this with vaccine than with toxin. Both vaccine and toxin often give rise to fever, passing away within 24 hours, and not infrequently produce a scarlatiniform erythema. He has also seen cases in which children have fallen ill with scarlet fever on the first day of the test, which seems to corroborate the view that the administration of toxin makes the disease come out whilst it is still in the stage of incubation. Whether in these cases it would have developed without this provocation remains an open question. Before making an inoculation the subject should always be thoroughly examined to make sure that there is no rise of temperature, or redness or discomfort of the throat. So far as therapeutics are concerned, Prof. Preisich considers that antitoxic serum, prepared with specific streptococci, is very efficacious. In cases which are serious at the outset, the administration of 10 c.cm. of serum causes a remarkable change in the condition: in 24–48 hours the rashes fade away and the fever is reduced, and does not reappear. Its prompt action is reminiscent of the effects of serum in diphtheria, and the treatment appears to influence desquamation and obviate complications. The only disadvantages are that the site of inoculation is painful for one or two days and the possibility of serum sickness. Prof Preisich is in hopes that the wider use of this serum will rob scarlet fever of its terrors and considerably reduce the mortality: but the price is at present so high that its general use is impossible.

PARIS.

(FROM OUR OWN CORRESPONDENTS.)

French Mortality in 1925.

THE statistician of the National Committee for Defence against Tuberculosis states that the death-rate in France has risen during 1925. Infantile mortality has been slightly greater: infectious diseases in Paris show some recrudescence; cancer is steadily increasing, and the figures show that malignant disease is tending to become as fatal to men as to women. Cerebral hæmorrhage and softening have become considerably commoner, and so have organic disease of the heart and cirrhosis of the liver. On the other hand, tuberculosis and affections of the respiratory tract show a certain decrease.

Malaria and Tuberculosis.

Marcou-Mutzner, of Ajaccio, reports that antagonism between malaria and tuberculosis is common in Corsica. When the diseases occur together the tuberculosis is apt to assume a protracted, sclerotic form, and there seems to be no reason why use should not be made of this fact in therapeutics. Cases of tuberculosis could be inoculated with *Plasmodium vivax*, when improvement might result from activation or shock therapy desensitising the tissues to the tubercle bacillus.

The Designation of Dentists.

French dentists demand to be called doctors in dental surgery as soon as they have completed the regular undergraduate work at the French universities, but physicians insist that no specialist shall receive official designation until he has finished the general courses in medicine required of all graduates and think that the present title of surgeon-dentist should be maintained. The question is being considered by the Ministry of Public Instruction.

Removal of Adenoids.

Prof. [illegible] of [illegible] employs a special [illegible] for removing adenoids in [illegible] of [illegible] 5 years old. The pharynx and [illegible] of the soft palate are [illegible]

Theatre. He said that the play had been chosen for performance that week as the directors thought that when guests had come to honour the work the Coombe Hospital was doing among the poor of Dublin, it was suitable to show them a play dealing with life in the Dublin tenements.

On the afternoon of Sept. 15th the guests paid a visit to the Coombe Hospital, and on the following day were present at a polo match in the Phœnix Park, where the Master of the Hospital captained one team. On Sept. 17th the Governors of the Hospital entertained some 300 guests to a garden party at the gardens of the Royal Zoological Society.

The Master of the Hospital and the Chairman, with their helpers, are to be congratulated on the success of the entire series of celebrations. Favoured with good weather all the guests appeared to enjoy their visit and spent a happy few days.

MEDICINE AND THE LAW.

Drug Addict Obtaining Prescriptions from Several Doctors Concurrently.

A FURTHER stage was reached at the Westminster police-court on Sept. 11th in the prosecution under the new Dangerous Drugs Regulations (promulgated last July) which attempt to restrain drug addicts from obtaining simultaneous prescriptions from several doctors. As previously stated, it is now an offence to obtain heroin and other dangerous compounds from more than one medical practitioner without disclosing the fact of the concurrent treatment by other doctors. The charge against the accused, an Eurasian, aged 44, was that he visited various doctors to obtain morphine compounds for hypodermic injection. The prosecution alleged that he had given the name of Lieut.-Colonel Radley, and also that of Colonel Rivett-Carnac, though he was in no way connected with the Rivett-Carnac family. At the previous hearing the magistrate adjourned the case in order to have the evidence of the medical practitioners. On the second stage of the case several doctors gave evidence. The medical evidence was not very fully recorded in the daily press, but the *Times* report summarises the testimony of a specialist who stated that he treated the defendant partly as a drug addict and partly for an inferior degree of asthma. The defendant alleged that he had been gassed during the war, and had been treated with different morphine preparations in Paris in such a manner that he came under the sway of the drug, so that a continued supply of it was the only thing which would alleviate his condition. The magistrate asked one of the medical witnesses what was the best thing to be done with the defendant, but the only suggestion made in reply was that the defendant would be better suited to a drier climate. The magistrate (Mr. Gill) was evidently puzzled to know how best to deal with the case, and granted a further remand to see if arrangements could be made for the defendant's departure from this country. Mr. Gill, it appears, observed that the offence was not as serious as a case of drug trafficking, and he indicated that he was ready to take a lenient course if it could be arranged that the defendant should go right away. While, however, it may be a convenient solution of this new problem to send an Eurasian back to the East, it remains to be seen how our magistrates will treat drug addicts who are natives of this country and who violate the new Regulations. Probably punishment in such cases will be similarly mitigated if defendants will undertake to enter some suitable institution or otherwise submit themselves to treatment under proper supervision. Parliament is inclined to treat addiction to drugs in the same way as addiction to alcohol; for example, a wife can now obtain a separation from a husband who is a habitual drug-taker in the same manner as if he were a habitual drunkard. But it is not certain that the public or the police-court magistrates are yet ready to accept drug-taking and drunkenness as involving identical penal consequences.

Sale of Milk. Deficiency of Milk Fat.

In a recent prosecution by the Norfolk County Council it was alleged that a farmer had sold milk which had the unusually heavy deficiency of 42 per cent. in milk fat. The magistrates dismissed the case upon what they described as a point of law, but it is not unreasonable to suggest that, if the law tolerates so large a deficiency, the law must be altered. It was pointed out by the prosecution that the Regulations made under the Food and Drugs Acts provide that, where a sample of milk contains less than 3 per cent. of milk fat, the law presumes that the milk is not genuine by reason of the abstraction of milk fat or the addition of water. The sample in this particular case contained as little as 1.74 per cent. Therefore the presumption arose that the milk was not genuine, the sample containing little more than half of the minimum amount of milk fat prescribed by the Sale of Milk Regulations. Thus the onus lay upon the farmer of proving that his milk was genuine. It appeared that, after the sample had been purchased, a statement was made to the inspector who had purchased it. This statement, which was confirmed on oath by the defendant before the magistrates, was to the effect that two cows in milk had calves, and that the method of milking was a partial milking for milk-selling purposes, the remaining milk being left for the calves. The prosecution alleged that this meant that the fore part of the milk went to the milk purchasers, while the rest, which was the richer in fat, was left for the benefit of the calves. The defendant stated that he had not been aware until that day that the fore part of milk differed in fat value from the remainder. He met the adverse presumption of non-genuineness by calling witnesses whose evidence traced the milk from the time it left the cows to the moment when the inspector obtained his sample. Under the legal decision in Grigg *v.* Smith, a case heard in the Divisional Court in 1917, milk may be proved genuine, even though there has been an exceptional course of milking, if it is proved that nothing is added or abstracted after the milk is taken from the cow. The decision in Grigg *v.* Smith does not countenance the view that it is an offence for a farmer to milk his cows in such a manner as to leave part of the milk for the calves. This is the point to which fresh legislation, either in the form of statute or of regulations, should be directed. The farmer in the recent case was able to rebut the presumption of non-genuineness by proving the history of the milk sample and showing that no fat had been abstracted and no water added. The chairman of the bench of magistrates, while dismissing the prosecution against the farmer (against whom no previous complaint had been made), observed that it would have been better if the farmer, seeing that his cows were feeding calves, had decided not to sell any milk from them. This observation might well form the foundation of a new legislative standard. The object of our Food and Drugs Acts, Milk and Dairies Acts and their accompanying regulations is to secure that what is sold as milk shall be good milk. The standard minimum of 3 per cent. of milk fat value is, like any other fixed percentage, an arbitrary figure which may require some marginal elasticity in administration, since, though Parliament and the public rightly insist upon protecting the interests of the consumer and particularly the interests of children and invalids, the farmer has a right to fair play. But it is disquieting to learn that a sample of milk containing a milk fat percentage of only 1.74 can find its way to the market without penalty. The *Eastern Daily Press*, which published an excellent account of the recent prosecution, described the line of defence as novel and successful. It is not actually novel, and it may be necessary for the legislature to provide that it shall not in future be successful.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the health statistics of the cities of Edinburgh and Newcastle-upon-Tyne for the year 1925:—

Name of city	Estimated mid-year population (R.G.).	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.	
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Heart disease.	Infant mortality.	Maternal mortality from childbirth.
Edinburgh ..	421,955	18·6	14·5	1·14	1·50	2·1	1·8	95	5·1
Newcastle-upon-Tyne ..	286,270	21·6	13·5	1·35	1·21	2·5	1·4	88	2·9

Edinburgh.

Dr. William Robertson reports a widespread prevalence of scarlet fever during the year. There were 2351 notifications with 62 deaths, and the disease was most prevalent during the last quarter of the year. Usually about 90 per cent. of the cases are removed to hospital, but during 1925 domiciliary treatment was encouraged when the circumstances were suitable and only 82 per cent. were removed to hospital. Following the Leith experience the stay in hospital has been reduced to four or five weeks. A puzzling outbreak occurred at a large boarding school for boys and appeared to be due to a "carrier" member of the staff, from whose fauces the *Streptococcus hæmolyticus* was recovered. The scheme for the immunisation of school-children against diphtheria has been continued without a single untoward result and has been extended to children of the pre-school age. The supply of insulin by the health department was begun on May 6th, 1924. About 100 phials are now given out every month, each containing 100 units. The total cost to the department after allowing for repayments has been about £100. Good results are reported from the use of mercury-vapour lamps for convalescents from measles and whooping-cough at the City Fever Hospital, and a mercury-vapour lamp and four open arc lamps have been installed at the surgical tuberculosis annexe, also with apparent success. Efforts to secure greater cleanliness of milk are being continued following on the milk competitions of the last two years. An illustration given in the report of 12 discs of cloth, through each of which 1 pint of milk has been filtered, shows an extraordinary variation in the dirt content. The City Council have decided to establish a tubercle-free herd at their farm for the supply of milk to the city hospitals. In order to get early information of cases of food poisoning the City Council has decided to pay a fee of 2*s.* 6*d.* to any medical practitioner for the immediate notification of such cases.

Dr. Robertson expresses his regret that with a view to the prevention of tuberculosis the slum problem was not taken in hand before any other housing scheme. Within the past three years two clearance schemes have been undertaken by the municipality, one in the Cowgate and Grass Market and the other in Leith. The condemned houses have had to remain in occupation owing to the slow progress made in providing alternative houses for the slum occupiers. Many of the slum dwellers show reluctance to leave their haunts and remove to a greater distance from their work. Alternative housing is under consideration for the third and largest improvement scheme in connexion with the S. Leonard's area. "The economic situation," says Dr. Robertson, "places a damper on housing ideals." Well-considered schemes of house-ownership make a strong appeal, and much more could be done to relieve the housing situation under the Small Dwellings Acquisition Act if local authorities would embark upon publicity campaigns. At present few people understand how to proceed. Dr. Robertson also favours the establishment of a decent municipal hostel where unmarried working men could be boarded for 25s. per week. The new two-storeyed houses with their provision of conveniences and surrounding space and opportunities at hand for recreation must be of extraordinary benefit to the younger generation when compared with the lofty tenements with their gloomy, ill-ventilated stairs, their facilities for the spread of infectious disease, and their aggregation of dwellings without adequate conveniences. Antenatal clinics are held at nine centres and the mothers of 52 per cent. of the infants born received some antenatal supervision during 1925. No damage to the eye was recorded from ophthalmia neonatorum.

Dr. John Guy, the tuberculosis officer, reports that the death-rate from pulmonary tuberculosis has remained practically stationary during the last five years, and he thinks this is due to the unsatisfactory state of industry. Dr. W. T. Benson states that the systematic immunisation of the nursing staff at the fever hospital against diphtheria, which was initiated in 1922, is being continued with very satisfactory results. Of the five nurses who contracted diphtheria during the year one had been proved susceptible but had not yet been immunised, three developed the disease within six weeks of the completion of the immunising course, and the fifth had a very mild attack one year after immunisation. All five recovered. Owing to the fact that immunity may take several months to develop, Dr. Benson thinks it would be better for the nurses to be immunised six months before taking up their hospital duties. The number of nurses who contracted scarlet fever was 15, and an attempt is being made to immunise those who are shown to be susceptible by the Dick test. Dr. W. T. Gardiner, the otologist, has been able to reduce the stay in hospital of both scarlet and diphtheria patients. During the year he performed 28 mastoid operations and did 125 removals of tonsils and adenoids.

Dr. David Lees shows that the attendance at the V.D. clinics continues to improve, thus the percentage of those who completed their treatment until considered to be cured during the last six years was as follows:—

1920	60·0 per cent.	1923	84·4 per cent.
1921	74·0	1924	88·1 ,,
1922	81·5	1925	88·7 ,,

The attempt to deal with the defaulters by confidential correspondence has not proved very successful, but in dealing with female defaulters the follow-up work of the child welfare department has been valuable. Excluding cases treated at the Royal Maternity Hospital about 16 per cent. of the patients require in-patient treatment, and more bed accommodation is needed, especially for married women and children. The attendances per new patient numbered 26. This may be compared with the figure of 30 for London, but the London report for 1925 gave no figure for the percentage of default, which in Edinburgh reached the low level of 11·8 during 1925. An appreciable amount of the Edinburgh default consists of seamen who must rejoin their ships. Patients are coming for treatment at an earlier stage of the disease. Gonorrhœa patients do not seek treatment as readily as syphilitic, perhaps because syphilis is regarded more seriously and the treatment of syphilis is more reliable and efficient. An increasing number of cases of vulvo-vaginitis was noted in 1925 and emphasises the need for personal cleanliness by patients with regard to towels, sponges, &c. Dr. Lees says with our present knowledge ophthalmia neonatorum can be stamped out.

The daily sale of "designated" milks in the city amounts to 218 gallons of "certified," 72 gallons of mounted on a 10 c cm syringe containing a 1 in 200 solution of novocaine, is then passed through the anæsthetised soft palate and the adenoid growth is infiltrated with the novocaine solution, which is injected at five points, effectively covering the adenoid area Five minutes after the local infiltration the adenoid may be painlessly removed by curettage

Homes for Mothers

With the object of reducing infantile mortality a group of Deputies has laid before the Chamber a Bill obliging departments to establish homes for mothers It is recommended that one or more of these institutions should be set up in every department as an annexe to the lying-in hospitals They are intended for all women partly or wholly breast-feeding their new-born babies, and also for those who wish to keep their confinement a secret Pregnant women whose condition requires special care would be admitted under exceptional circumstances, and it is intended that mothers should remain in the homes for as long as their own or their babies' health may make it desirable They would receive a daily allowance, and the fact that they were in hospital would be no obstacle to their receiving payments to which the law entitled them

Death of Two Physicians

The death is announced of Prof C Oddo, well known for his work in pathology and clinical medicine at the University of Marseilles, and author of works on spinal and medullar affections, emergency medicine, and occupational accidents

Dr Georges Thibierge, who died on August 24th, was one of the most brilliant French dermatologists He edited the *Annales de Dermatologie*, and was President of the French Society of Dermatology, and Secretary of the Society of Legal Medicine

Congresses and Post-graduate Courses

The Thirteenth International Congress of Hygiene will be held from Oct 19th to 21st at Paris under the presidency of Mr Henri Martel Applications for membership will be received by Mr Bossus, 142, Boulevard de Montparnasse, Paris, 14e

The Thirty-fifth French Surgical Congress will be held at the Faculté de Médecine, Paris, from Oct 4th to 9th Jean Louis Faure will preside

Dr. Gunsett, director of the cancer centre at Strasbourg, has organised a course dealing with the practical details of diagnosis and treatment of cancer It will last from Oct 18th to Nov 6th, the number of students is limited and there are few vacancies left Particulars from Dr Gunsett, Hôpital Civil, Strasbourg

A course in radiology will be given by Béclère from Oct 18th to Nov 13th at the Curie Foundation with supplementary practical work at the Hôpital St Antoine Applications to Dr Solomon at the hospital

Journées Médicales are to be held at Montpellier from Nov. 4th to 6th Information may be had from Dr. Desfour, 8 rue Emile Zola, Montpellier, Hérault.

A course in cardiology will be given from Oct 11th to 27th by Dr Laubry and his associates Application to Mr D Routier, Hôpital Broussais, 96 rue Didot, Paris

A Sanatorium at Havre

A new institution has been opened at Havre for those damaged by asphyxiating gases during the war It will also take cases of tuberculosis, for which there are only some 15,000 beds available in France to serve 680,000 sufferers The new sanatorium has been erected by private subscription and it is hoped that similar efforts may be made in other places

A new hæmocytometer, devised by Dr Bécart, contains cell-count pipettes in which dilution is made easier and more exact by means of a supplementary air chamber, pierced by a hole The orifice is closed by the finger during aspiration, ascent of the column of liquid being immediately arrested by removing the finger from the hole The diluting chamber ends in a capillary lumen, which adds still further to ease and exactness

The Paris Court of Appeals has issued a decision making it clearly illegal to publish and sell notes of lectures delivered by professors attached to medical or other faculties This is a sequel to an action taken by several professors against a person who offered notes in medicine and pharmacology for sale to students A fine was inflicted

Dr Pagniez has reported to the Société Médicale des Hôpitaux de Paris a colour reaction given by the urine in cases of spirochætal jaundice An emerald-green colour develops when the urine is treated, as in testing for albumin, by heat and acetic acid, and this reaction is said to be specific

Prof Cunéo, especially known for his work in bone surgery, has been sent by the French Government to Colombia where he will give addresses on surgery

The price of bread is not always rising in France, and in Paris the official price is now 2 55 francs per kilo The proportion of foreign wheat which may be mixed with French wheat, for making flour, is prescribed at 40 per cent Following the slight reduction of the official price bakers at St Malo have declared a strike A grain census is to be taken and grain stocks registered

IRELAND

(FROM OUR OWN CORRESPONDENTS)

Public Hospitals and Medical Fees

Dr A D Clinch, one of the medical inspectors of the Department of Local Government and Public Health, held a severe inquiry last week at Scariff District Hospital, co Clare, into complaints which had been made that the medical officer had demanded fees from patients treated in the hospital It appears that it is the custom for well-to-do patients to pay the full cost of their maintenance in the hospital, and the medical officer holds that in such cases he is entitled to charge a reasonable fee for his services In this view he is supported by the medical profession of the county On the other hand, certain members of the county board of health maintain that the medical officer is paid a salary to cover attendance on all patients admitted to the hospital, and that no fee should be charged for treatment given in a public institution Two patients gave evidence that they were willing to pay the doctor a fee, but that they thought the fee he demanded was excessive—the principle of payment being thus conceded They were cross-examined as to their means, while the medical officer denied having refused treatment to any patient on the ground of a fee, or the right fee, not being forthcoming The inspector gave it as his personal opinion that a doctor could properly accept a fee from a patient who was liable for full maintenance charges.

Royal Victoria Hospital, Belfast

The Governor of Northern Ireland will inaugurate on Oct 20th the new extensions which have been under erection for over three years, and are now complete They include two new units with 80 beds, a new nurses' home, three new operating theatres, several new class-rooms, additional accommodation for the ophthalmic, radiological, dental, and other departments, and a new mortuary The cost has been approximately £119,000

Belfast Mental Hospital

The annual report of the Belfast Mental Hospital for 1925 shows that there were 1260 patients under treatment during the year—632 males and 628 females The most prevalent form of mental disorder was melancholia (28 3 per cent), followed by primary dementia (15 per cent.), there were 25 cases of general paralysis of the insane—20 males and 5 females The most potent factor in causation was found to be a faulty heredity, the other chief causes being mental stress, the critical periods, and syphilis Alcoholic excess was found to be a contributory cause in 7 1 per cent of the admissions, and in 6 cases it was believed to be the principal cause Great attention was paid to the employment of patients, both male and female, the benefit of which "cannot be overestimated" The report calls attention to the need for the revision of the Lunacy Laws, and anticipates important assistance in this matter from the report of the Departmental Commission in Lunacy Reform It regards early treatment without loss of liberty as one of the most important measures

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

The following are some of the health statistics of the cities of Edinburgh and Newcastle-upon-Tyne for the year 1925:—

Name of city.	[illegible]	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.	
			All causes.	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
Edinburgh ...	423,968	18.4	13.5	1.4	2.1	2.1	3.1	96	7.1
Newcastle-upon-Tyne...	286,700	22.0	13.7	1.7	1.1	2.5	1.[illegible]	86	2.9

Edinburgh.

Dr. William Robertson reports a widespread prevalence of scarlet fever during the year. There were 2871 notifications with 42 deaths, and the disease was most prevalent during the last quarter of the year. Usually about 80 per cent. of the cases are removed to hospital, but during 1925 domiciliary treatment was encouraged when the circumstances were suitable and only 52 per cent. were removed to hospital. Following the Leith experience the stay in hospital has been reduced to four or five weeks. A puzzling outbreak occurred at a large boarding school for boys and appeared to be due to a "carrier" member of the staff, from whose fauces the *Streptococcus haemolyticus* was recovered. The scheme for the immunisation of school-children against diphtheria has been continued without a single untoward result and has been extended to children of the pre-school age. The supply of insulin by the health department was begun on May 6th, 1924. About 100 phials are now given out every month, each containing 100 units. The total cost to the department after allowing for repayments has been about £300. Good results are reported from the use of mercury-vapour lamps for convalescents from measles and whooping-cough in the City Fever Hospital; and a mercury-vapour lamp and four open arc lamps have been installed at the surgical tuberculosis annexe also with apparent success. Efforts to secure greater cleanliness of milk are being continued, following on the milk competitions of the last two years. An illustration given in the report of 12 discs of cloth through each of which 1 pint of milk has been filtered, shows an extraordinary variation in the dirt content. The City Council have decided to establish a tubercle-free herd at their farm for the supply of milk to the city hospitals. In order to get early information of cases of food poisoning the City Council has decided to pay a fee of 2s. 6d. to any medical practitioner for the immediate notification of such cases.

Dr. Robertson expresses his regret that with a view to the prevention of tuberculosis the slum problem was not taken in hand before any other housing scheme. Within the past three years two clearance schemes have been undertaken by the municipality, one in the Cowgate and Grass Market and the other in Leith. The condemned houses have had to remain in occupation owing to the slow progress made in providing alternative houses for the slum occupiers. Many of the slum dwellers show reluctance to leave their haunts and remove to a greater distance from their work. Alternative housing is under consideration for the third and largest improvement scheme in connexion with the St. Leonard's area. "The economic situation," says Dr. Robertson, "places a damper on housing ideals." Well-considered schemes of house-ownership make a strong appeal, and much more could be done to relieve the housing situation under the Small Dwellings Acquisition Act if local authorities would embark upon publicity campaigns. At present few people understand how to proceed. Dr. Robertson also favours the establishment of a decent municipal hostel where unmarried working men could be boarded for 25s. per week. The new two-storied houses with their provision of conveniences and surrounding space and opportunities at hand for recreation must be of extraordinary benefit to the younger generation when compared with the lofty tenements with their gloomy, ill-ventilated stairs, their facilities for the spread of infectious disease and their aggregation of dwellings without adequate conveniences. Antenatal clinics are held at nine centres and the mothers of 12 per cent. of the infants born received some antenatal supervision during 1925. No damage to the eye was recorded from ophthalmia neonatorum.

Dr. John Guy, the tuberculosis officer, reports that the death-rate from pulmonary tuberculosis has remained practically stationary during the last five years, and he thinks this is due to the unsatisfactory state of industry. Dr. W. T. Benson states that the systematic immunisation of the nursing staff at the fever hospital against diphtheria, which was initiated in 1922, is being continued with very satisfactory results. Of the five nurses who contracted diphtheria during the year one had been proved susceptible but had not yet been immunised, three developed the disease within six weeks of the completion of the immunising course, and the fifth had a very mild attack one year after immunisation. All five recovered. Owing to the fact that immunity may take several months to develop Dr. Benson thinks it would be better for the nurses to be immunised six months before taking up their hospital duties. The number of nurses who contracted scarlet fever was 15, and an attempt is being made to immunise those who are shown to be susceptible by the Dick test. Dr. W. T. Gardiner, the otologist, has been able to reduce the stay in hospital of both scarlet and diphtheria patients. During the year he performed 28 mastoid operations and did 125 removals of tonsils and adenoids.

Dr. David Lees shows that the attendance at the V.D. clinics continues to improve, thus the percentage of those who completed their treatment until considered to be cured during the last six years was as follows:—

1920 ...	60.0 per cent.	1923 ...	84.4 per cent.
1921 ...	74.0 "	1924 ...	85.1 "
1922 ...	81.5 "	1925 ...	88.7 "

The attempt to deal with the defaulters by confidential correspondence has not proved very successful, but in dealing with female defaulters the follow-up work of the child welfare department has been valuable. Excluding cases treated at the Royal Maternity Hospital about 15 per cent. of the patients require in-patient treatment, and more bed accommodation is needed especially for married women and children. The attendances per new patient numbered 30. This may be compared with the figure of 36 for London, but the London report for 1925 gave no figure for the percentage of default, which in Edinburgh reached the low level of 11.3 during 1925. An appreciable amount of the Edinburgh default consists of seamen who must rejoin their ships. Patients are coming for treatment at an earlier stage of the disease. Gonorrhoea patients do not seek treatment as readily as syphilitic, perhaps because syphilis is regarded more seriously and the treatment of syphilis is more reliable and efficient. An increasing number of cases of vulvo-vaginitis was noted in 1925, and emphasises the need for personal cleanliness by patients with regard to towels, sponges, &c. Dr. Lees says with our present knowledge ophthalmia neonatorum can be stamped out.

The daily sale of "designated" milks in the city amounts to [illegible] gallons of "certified," 72 gallons of mounted on a 10 c cm syringe containing a 1 in 200 solution of novocaine, is then passed through the anæsthetised soft palate and the adenoid growth is infiltrated with the novocaine solution, which is injected at five points, effectively covering the adenoid area Five minutes after the local infiltration the adenoid may be painlessly removed by curettage

Homes for Mothers

With the object of reducing infantile mortality a group of Deputies has laid before the Chamber a Bill obliging departments to establish homes for mothers It is recommended that one or more of these institutions should be set up in every department as an annexe to the lying-in hospitals They are intended for all women partly or wholly breast-feeding their new-born babies, and also for those who wish to keep their confinement a secret Pregnant women whose condition requires special care would be admitted under exceptional circumstances, and it is intended that mothers should remain in the homes for as long as their own or their babies' health may make it desirable They would receive a daily allowance, and the fact that they were in hospital would be no obstacle to their receiving payments to which the law entitled them

Death of Two Physicians

The death is announced of Prof C Oddo, well known for his work in pathology and clinical medicine at the University of Marseilles, and author of works on spinal and medullar affections, emergency medicine, and occupational accidents

Dr Georges Thibierge, who died on August 24th, was one of the most brilliant French dermatologists He edited the *Annales de Dermatologie*, and was President of the French Society of Dermatology, and Secretary of the Society of Legal Medicine

Congresses and Post-graduate Courses

The Thirteenth International Congress of Hygiene will be held from Oct 19th to 21st at Paris under the presidency of Mr Henri Martel Applications for membership will be received by Mr Bossus, 142, Boulevard de Montparnasse, Paris, 14^{e}

The Thirty-fifth French Surgical Congress will be held at the Faculté de Médecine, Paris, from Oct 4th to 9th Jean Louis Faure will preside

Dr Gunsett, director of the cancer centre at Strasbourg, has organised a course dealing with the practical details of diagnosis and treatment of cancer It will last from Oct 18th to Nov 6th, the number of students is limited and there are few vacancies left Particulars from Dr Gunsett, Hôpital Civil, Strasbourg

A course in radiology will be given by Béclère from Oct 18th to Nov 13th at the Curie Foundation with supplementary practical work at the Hôpital St Antoine Applications to Dr Solomon at the hospital

Journées Médicales are to be held at Montpellier from Nov 4th to 6th Information may be had from Dr Desfour, 8 rue Emile Zola, Montpellier, Hérault

A course in cardiology will be given from Oct 11th to 27th by Dr Laubry and his associates Application to Mr D Routier, Hôpital Broussais, 96 rue Didot, Paris

A Sanatorium at Havre

A new institution has been opened at Havre for those damaged by asphyxiating gases during the war It will also take cases of tuberculosis, for which there are only some 15,000 beds available in France to serve 680,000 sufferers The new sanatorium has been erected by private subscription and it is hoped that similar efforts may be made in other places

A new hæmocytometer, devised by Dr Bécart, contains cell-count pipettes in which dilution is made easier and more exact by means of a supplementary air chamber, pierced by a hole The orifice is closed by the finger during aspiration, ascent of the column of liquid being immediately arrested by removing the finger from the hole The diluting chamber ends in a capillary lumen, which adds still further to ease and exactness

The Paris Court of Appeals has issued a decision making it clearly illegal to publish and sell notes of lectures delivered by professors attached to medical or other faculties This is a sequel to an action taken by several professors against a person who offered notes in medicine and pharmacology for sale to students A fine was inflicted

Dr. Pagniez has reported to the Société Médicale des Hôpitaux de Paris a colour reaction given by the urine in cases of spirochætal jaundice An emerald-green colour develops when the urine is treated, as in testing for albumin, by heat and acetic acid, and this reaction is said to be specific

Prof Cunéo, especially known for his work in bone surgery, has been sent by the French Government to Colombia where he will give addresses on surgery

The price of bread is not always rising in France, and in Paris the official price is now 2 55 francs per kilo The proportion of foreign wheat which may be mixed with French wheat, for making flour, is prescribed at 40 per cent Following the slight reduction of the official price bakers at St Malo have declared a strike A grain census is to be taken and grain stocks registered

IRELAND

(FROM OUR OWN CORRESPONDENTS)

Public Hospitals and Medical Fees

Dr A D Clinch, one of the medical inspectors of the Department of Local Government and Public Health, held a severe inquiry last week at Scariff District Hospital, co Clare, into complaints which had been made that the medical officer had demanded fees from patients treated in the hospital It appears that it is the custom for well-to-do patients to pay the full cost of their maintenance in the hospital, and the medical officer holds that in such cases he is entitled to charge a reasonable fee for his services In this view he is supported by the medical profession of the county On the other hand, certain members of the county board of health maintain that the medical officer is paid a salary to cover attendance on all patients admitted to the hospital, and that no fee should be charged for treatment given in a public institution Two patients gave evidence that they were willing to pay the doctor a fee, but that they thought the fee he demanded was excessive—the principle of payment being thus conceded They were cross-examined as to their means, while the medical officer denied having refused treatment to any patient on the ground of a fee, or the right fee, not being forthcoming The inspector gave it as his personal opinion that a doctor could properly accept a fee from a patient who was liable for full maintenance charges

Royal Victoria Hospital, Belfast

The Governor of Northern Ireland will inaugurate on Oct 20th the new extensions which have been under erection for over three years, and are now complete They include two new units with 80 beds, a new nurses' home, three new operating theatres, several new class-rooms, additional accommodation for the ophthalmic, radiological, dental, and other departments, and a new mortuary The cost has been approximately £119,000

Belfast Mental Hospital

The annual report of the Belfast Mental Hospital for 1925 shows that there were 1260 patients under treatment during the year—632 males and 628 females The most prevalent form of mental disorder was melancholia (28 3 per cent), followed by primary dementia (15 per cent), there were 25 cases of general paralysis of the insane—20 males and 5 females The most potent factor in causation was found to be a faulty heredity, the other chief causes being mental stress, the critical periods, and syphilis Alcoholic excess was found to be a contributory cause in 7 1 per cent of the admissions, and in 6 cases it was believed to be the principal cause Great attention was paid to the employment of patients, both male and female, the benefit of which "cannot be overestimated" The report calls attention to the need for the revision of the Lunacy Laws, and anticipates important assistance in this matter from the report of the Departmental Commission on Lunacy Reform It regards early treatment without loss of liberty as one of the most important measures

Hospital. So far not more than a single case has occurred in any one house, and these have been widely scattered all over the city. Careful investigations have been made, but, so far, practically no connexion between the cases has been traced. Hitherto, this disease has caused little trouble in Leicester, the largest number notified in any one year since the disease was made notifiable was 12 in the year 1924. Under normal conditions however, Dr. Millard adds, it is probable that a good many cases escape notification, the disease being so rare that medical men forget that it is notifiable. At the present time all the medical practitioners having been circularised as to the existence of the outbreak cases are, no doubt, coming to light which normally would not be recognised or reported.

SCHOOL MEDICAL SERVICE.

* Excluding dental defects and uncleanliness.

Bristol.

THE report of Dr. R. A. Askins for 1925 to the Education Committee shows the existence in Bristol of close coöperation between the infant welfare department and the school medical service, ensuring a valuable continuity of medical history. Sixty-two children were referred from the department to the school eye clinics on account of squint. Dr. R. R. Garden gives an account of the orthoptic treatment of concomitant squint. He comments on the serious loss of sight which results from neglected unilateral convergent squint of the concomitant type and emphasises the need for treatment in the earliest stages. In six early cases the squint had existed only a short time and the mere wearing of suitable spectacles was sufficient to effect a cure. In 22 cases where there was serious impairment of vision in the squinting eye orthoptic treatment had been given for some months with the results that in 12 cases, vision had been restored to normal or to within one line of normal (Snellen or picture test types) as compared with the fixing eye. In 10 cases the vision was markedly improved. There is also a scheme in Bristol whereby expectant mothers and children under 5 years of age have dental treatment at the school clinics. The Education Committee maintain two schools for feeble-minded children and the total number on the registers at the end of the year was 246. Thirty-seven cases were notified under the Mental Deficiency Act to the local committee during the year—16 boys and 21 girls. Dr. Garden relates in detail 40 cases of encephalitis lethargica and its sequelæ with their condition in February, 1925, and again in February, 1926. The changes for better or worse, which some of these children show, suggest that those are right who regard the late symptoms as not really residua or after-effects, but signs that the acute disease is followed in many cases by a chronic stage. The interesting section by Dr. J. Morrison at the end of the report on the influence of environment in the causation of rheumatic heart disease is dealt with on p. 659 of this issue.

St. Helens.

Dr. Frank Hauxwell's report shows that the work, so far as the existing facilities admit, has been well carried out and 84·1 per cent. of defects referred for treatment received it during the year. Those responsible for the welfare of the children in St. Helens have been slow to appreciate the value, both socially and economically, to the community of providing special facilities for weakly and abnormal children. The percentage of parents attending medical inspections is a fair index of the interest taken by the lay public in the medical work, and Dr. Hauxwell states the attendance of parents has always been poor. A bold policy often stimulates public interest, and the adoption of the plans for the first open-air school and for the new orthopædic scheme will certainly benefit both the children and the community in general. The bogey of the parents' objection to special schools for the feeble-minded has been exposed in many urban districts and should not deter a trial in St. Helens. Dr. Hauxwell attributes the falling off in the general health of the children to industrial depression and bad housing, aggravated by improper feeding and the prevalence of infectious diseases (measles and whooping-cough). A table giving percentages of malnutrition in each year since 1920 shows that during the coal strike year 1921 when 1,337,576 meals were supplied to school-children, the malnutrition figure fell to 0·6 per cent., as against 1·5 per cent. in the previous year. This was the lowest percentage of any of the five years, which may be used as an argument for the necessity of arousing the interest of parents in the welfare of their children. Communal meals and libations of cod-liver oil cannot permanently do away with the responsibilities of parents or make it less essential for them to master the fundamentals of home hygiene.

Nottingham.

Dr. E. M. Wyche looks upon his report as an annual stocktaking, a sort of index of departmental efficiency and progress. And he succeeds in holding the interest not only of the specialist but also of the layman when he sketches out the special needs of the locality, the circumstances which have shaped the policy, and the degree of success already obtained. His whole-hearted belief in Nature's therapy of open-air and sunlight is justified by the results obtained at the six open-air schools of the city and the new open-air school at the Arboretum, which is the last word in such things. Dr. Wyche rightly holds that while the ideal must still be aimed at yet the love of fresh air, sunlight, and cleanly habits can be instilled all day and every day at every school. The personality of the head teacher and his interest in the welfare of the children is a large factor in the promotion of school medical work, but zeal in the medical officer begets enthusiasm in both teachers and parents, and there is no branch of school medical work in Nottingham which lags behind. The method of ascertainment of defects is set out in the report: cases for removal of tonsils and adenoids are carefully sifted, and weakly children are toned up by exposure to ultra-violet rays for a few weeks prior to operation, after which they remain in hospital for two days. Ionisation is the accepted method in treating discharges from ears and noses, and increased facilities for dental treatment are being provided. The orthopædic scheme is now in working order and promises well, though the shortage of hospital schools is a difficulty. Dr. Wyche believes that, apart from hereditary tendency to myopia, this defect is definitely arrested by residence in an open-air school. The sifting of all abnormal children, each into the special school or class designed for his peculiar needs, be he blind, deaf, cripple, or feeble-minded, is thorough. For instance, all 7-year-olds are submitted by the head teacher to standardised tests for intelligence, and there are 37 classes for dull and backward children alone.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED SEPT. 11TH, 1926.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 103 (last week 79); scarlet fever, 1275; diphtheria, 863; enteric fever, 74; pneumonia, 413; puerperal fever, 31; cerebro-spinal fever, 6; acute poliomyelitis, 53; encephalitis lethargica,

(Continued at foot of next page.)

Grade A (tuberculin-tested), 2 gallons of Grade A, and 5815 gallons of pasteurised, a total of 6137 gallons The daily consumption of "non-designated" milk amounts to 15,298 gallons, of which 3089 are sold in bottles The cow population of the city byres is about 4300 and, among these, 15 cases of tubercle of the udder and 11 of advanced tuberculosis were found during 1925 Of 74 samples of mixed milk examined for tubercle, 6 gave a positive result equal to 8 8 per cent The average percentage of tuberculous milk samples for the last eight years is approximately 8 6 per cent, exactly the same as that for the city of Manchester during the last 14 years

Newcastle

Dr Harold Kerr reports that 206 cases of encephalitis lethargica have been treated in Newcastle between 1919 and 1925 Of these, 68 died, 60 were left with mental or permanent nervous impairment, 64 recovered, and 14 have removed to an unknown address The special work of Dr Neil Maclay, the oto-rhinologist, visiting at the city fever hospital, has now been carried on since 1921 Sixteen per cent of the scarlet fever cases have developed nose or ear infections with occasional mastoid involvement Thirty-three cases needed operation and their stay in hospital averaged only 14 days from the development of the complication as compared with 25 days in the case of those treated by conservative methods Dr S J Clegg has continued the use of prophylactic vaccines prepared from organisms present in the nasal and ear discharges of scarlet fever patients Of 337 cases treated on admission with these vaccines, 10 per cent developed nose or ear discharge, while of the remaining 699 not so treated 19 per cent developed one or other of these complications The scarlet fever antitoxin obtained from horses on similar lines to diphtheria antitoxin has been tried, and appeared to give unusually good results in severe septic cases A further prophylactic measure used in the diphtheria wards has been the inoculation of patients with ordinary polyvalent anti-streptococcus serum, and this appears to have been successful in preventing "cross" infection with scarlet fever The Schick test followed by immunisation when necessary is used for all members of the staff in the diphtheria pavilions The "Dick" reaction has also been used experimentally but has not yet become a routine measure The average stay in hospital for scarlet fever cases is now 37 3 days, as compared with 56 days less than 20 years ago, and there is no doubt, says Dr Kerr, that much of this shortening is due to the advance in vaccine and serum therapy Little use is now made of chemical disinfectants, the expenditure for the year on this item being only £62, of which £16 was for the hospitals Reliance is chiefly placed on steam disinfection of bedding, clothing, &c, and on thorough cleansing

The V D. clinic is established in the skin department of the Royal Victoria Infirmary under the charge of Sir Robert Bolam There is a drop in new cases, especially syphilis Thus in 1921 there were 534 new cases of syphilis and in 1925 only 286 The figures for gonorrhœa and soft chancre were 489 and 40 respectively in 1921, and 466 and 34 in 1925 The attendance per case has risen from 10 9 in the earlier year to 17 4 in the later The irrigation station is largely used Thirty-nine per cent of patients ceased to attend before treatment was completed (the Edinburgh figure was 11 3), and of these 475 out of 588 defaulted before their first course of injections was completed The notifications of ophthalmia neonatorum have fallen from 116 in 1920 to 50 in 1925 Of 321 registered blind persons in Newcastle to-day 71 are stated to have been blind from birth, but there are only three blind children under 5 years of age

The number of antenatal sessions has been increased from 74 in 1920 to 319 in 1925 The medical officers who preside at these sessions are chosen from among the practitioners who specialise in gynæcology and whose ability to deal with this class of work is particularly reliable The maternal mortality from childbirth has fallen from 3 3 per 1000 births in 1921 to 2 9 in 1925, the English rate being about 4 These comparatively satisfactory figures are largely due to the work of the Princess Mary Maternity Hospital which deals with about one-third of all the births in the city The remaining two-thirds of the births are managed in about equal proportions by medical practitioners and midwives Since 1921, when in the name of economy the number of health visitors was reduced from 20 to 12, there has been a gradual recovery and there are now 18 health visitors Voluntary workers play an important part and run a nursery school at St Peter's Centre and propose to establish similar schools in two other centres

Dr Kerr draws attention to "the inevitable increase in tuberculosis that follows within a couple of years or so of a period of financial depression" Thus the rate from pulmonary tuberculosis which was 1 25 in 1921, 1 14 in 1922, and 1 10 in 1923, rose to 1 12 in 1924 and 1 20 in 1925 There are not enough patients in the curable stage to fill the beds at Barrasford Sanatorium, whilst there were too many for the 62 beds for advanced cases at Walker Gate To meet the latter want another pavilion was added for advanced cases in 1922 The health committee leases 30 beds at Stannington Sanatorium for children where the average stay for boys was 313 days and for girls 199 Most of the surgical tuberculosis is dealt with by the general hospitals and the health committee will in the near future have to face the establishment of a special institution for surgical tuberculosis or the subsidising of one or more of the general hospitals Out of 372 samples of milk examined for tubercle 29 (equal to 8 per cent) gave a positive result

Newcastle consumes daily 10,000 gallons of milk equivalent to a small teacupful per head of the population Only 1500 gallons are produced in the neighbourhood, the remainder comes from Cumberland, Westmorland, Dumfriesshire, and Ayrshire, and a small amount from Northumberland From 400 to 500 gallons of graded milk are sold, of which 30 are "certified" and the remainder "Grade A (tuberculin tested)" The only two institutions in the city which use graded milk are the Fever Hospital and the open-air school

A more satisfactory addition has been made to the housing accommodation during the past year, 1177 houses having been completed and many hundreds being under construction at the close of the year Private enterprise contributed 385 of the total In spite of this improvement there is still gross overcrowding, profiteering by sub-letters, and the exploitation of so-called furnished lodgings A beginning has been made with the clearing of one of the three condemned areas Dr Leonard Hill's kata-thermometer being used with success for improving the ventilation of cinemas and theatres Eighty-four tests were made in 37 buildings The only buildings which gave a satisfactory result were 16 cinemas in which a mechanical system of ventilation was installed

POLIOMYELITIS IN LEICESTER

THE outbreak of acute poliomyelitis in Leicestershire affects both the city and county As far as the city is concerned Dr C Killick Millard informs us that the first case was reported in May This was followed by isolated cases until in August a sharp increase occurred, and during that and the present month over 40 cases have been reported, while additional cases have been discovered by the health department The majority of the cases have been, as usual, in children under 5, but there have been a considerable number in older children and several cases in adults There have been some half dozen deaths, chiefly of the fulminating type, the cases proving rapidly fatal within a few days of the onset Cases have been admitted to the Leicester Royal Infirmary and a special ward has now been opened at the City Isolation

SANATORIUM TREATMENT OF TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—Your annotation of Sept. 11th [illegible] on Messrs. Stocks and Karn's inquiry into the value of sanatorium treatment for pulmonary tuberculosis refers to the surprising result that amongst the patients dealt with those who have been in a sanatorium eventually fared worse than those who had not. There is, I think, a reasonable explanation.

An average favourable case of pulmonary tuberculosis needs from one to two years' treatment, and those who are stated to have been treated in a sanatorium seldom spend more than a few months of this time in the institution, all the remainder consisting of home treatment. The latter will have much more influence over the final result than the relatively short spell of sanatorium treatment; and as patients are sent to a sanatorium chiefly because the home conditions are unfavourable or unsuitable for treatment there, those treated in a sanatorium will have less favourable home conditions than those treated entirely at home, and will show correspondingly poorer results. The contrast will be greater in proportion to the unsuitability of the homes, and will be less apparent in only early favourable cases, because these will be more completely restored in the short time available for sanatorium treatment.

We may conclude, not that sanatorium treatment is waste of time and money, but that only favourable cases should receive prolonged treatment, first at a sanatorium and then in a medically-supervised home. In proportion as the latter is made to resemble hygienically a good sanatorium, so will the time necessary for sanatorium treatment be reduced and the chance of subsequent relapse diminished. I do not wish to minimise the value of the inquiry referred to, but to prevent fallacious conclusions being drawn therefrom. I am, Sir, yours faithfully,

Farnham, Surrey, Sept. [illegible], 1926. F. R. WALTERS.

TUBERCULIN DISPENSARIES.

To the Editor of THE LANCET.

SIR,—Will you kindly allow me to ask through the medium of your columns if perchance there is now a tuberculin dispensary in Brighton where a patient going out from Rudgwick Sanatorium may receive treatment with tuberculin on the intensive system, as taught by Dr. Camac Wilkinson in 1910 and following years. I can hardly imagine a place of the size and importance of Brighton not having a public tuberculin dispensary, and there must surely be some of the many doctors there who are proficient in the method, but I cannot find anyone who is known to be an expert in this treatment.

I, personally, have followed out his method of treatment ever since we opened our Clapham Tuberculin Dispensary in April, 1911, and am more than convinced that up to the present time no other treatment can give anything like such good results, and I have worked at Rudgwick ever since 1898. If this treatment is begun early about 90 per cent. recover completely and that without having to give up their daily work, which is so important.

In London, now that Dr. Camac Wilkinson has returned, this early treatment may be obtained at 32, Fitzroy-street, Fitzroy-square, Tottenham Court-road, W.C., on Mondays and Thursdays at 9–11 A.M., and doctors are all welcomed to come and learn it; but other towns should surely be able to work out such a system, so that patients everywhere may get the benefit.—I am, Sir, yours faithfully,

ANNIE MCCALL, M.D., &c.,
Chairman and Director of Clapham Maternity
Hospital and Affiliated Institutions.

Clapham-road, London, S.W., Sept. 21st, 1926.

*** Is there any reason to doubt that the facilities for the treatment advocated will follow upon the general acceptation by the medical profession of their need?—ED. L.

CASTOR OIL VERSUS SALINE APERIENT.

To the Editor of THE LANCET.

SIR,—In view of the [illegible] under the above heading in THE LANCET of July 3rd and [illegible] of the very great [illegible] oil in the early stages of acute bacillary dysentery, I submit the following figures in the hope that they may encourage further trials of this treatment.

Between October, [illegible] and September, [illegible] I treated [illegible] per cent. Between October, [illegible] and March, [illegible] I made use of the castor oil treatment [illegible] per cent.—most of these [illegible] however [illegible] only in the cases [illegible] how best to apply the treatment. In my last [illegible] cases there has been no death [illegible] those cases [illegible]

Full particulars of this treatment, its rationale, and results are given in an article in the [illegible] *Medical Journal* (August, [illegible]) by myself and my valued late assistant, Mr. C. J. [illegible], to which Dr. [illegible] most kindly refers in his letter in THE LANCET of July [illegible]. Possibly [illegible] would prove as useful as castor oil [illegible]—I am, Sir, yours faithfully,

T. R. [illegible], M.R.C.S., L.R.C.P. [illegible]

Medical Superintendent [illegible]

[illegible], August [illegible], 1926.

HELIOTHERAPY IN PULMONARY TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—I have followed with interest Dr. J. [illegible] Wood's article and Dr. F. C. Chandler's letter on this subject. The conditions for heliotherapy at Montana are practically identical with those at Leysin, and we are using this treatment more and more extensively in pulmonary cases. With febrile patients the amount of exposure has to be so small and the time required for pigmentation is so long that sun-baths are rarely employed. Short air-baths on the feet and legs are more useful in such cases. Sun-baths are only used extensively when the temperature has been brought down to normal by rest, artificial pneumothorax, sanocrysin, or other means.

The majority of afebrile patients benefit from heliotherapy, but dangerous reactions are liable to follow faulty technique, especially too early exposure of the diseased part. To avoid this danger the following method is used. The feet, legs, and abdomen are exposed according to Rollier's technique. About a month later, when these parts are sufficiently pigmented, the chest is first exposed for two to five minutes. The time of exposure is increased gradually up to one to two hours. As a rule it is not wise to give more than two hours' exposure to Alpine sunlight in pulmonary cases. Rollier's practice in avoiding sun-baths when the air temperature is high should be carefully observed. In summer the early morning hours give the best conditions for heliotherapy. In winter sun-bathing may be carried out at any time of day as the air temperature is always low and the intensity of the sunlight is increased by reflection from the snow.

Although much less striking than in surgical cases, the results so far obtained are encouraging. Besides increasing the appetite and improving the nutrition of skin and muscles, heliotherapy has a psychic effect which is often of considerable benefit. Recently the treatment of surgical tuberculosis has been copied still further, and with certain cases hydrotherapy has been added to heliotherapy. In a few of the more robust patients this combination of sun- and lake-bathing appears to have a beneficial effect.

I am, Sir, yours faithfully,

ANDREW MORLAND.

Palace Sanatorium, Montana, Switzerland,
Sept. 17th, 1926.

Correspondence.

"Audi alteram partem"

PASTEURISATION OF MILK

To the Editor of The Lancet

Sir,—So far as I am aware, not the most ardent advocate of pasteurisation fails to recognise and insist that pure raw milk is the best But the whole point, the sole foundation, for the advocacy of pasteurisation, lies in the simple well-ascertained fact that pure raw milk is not available in this country for the people Even Grade A Certified Milk does not comply with this simple definition Such milk, under the Order, may contain 30,000 bacteria per c cm, and the colon bacillus in less than 0 1 c cm

I find it difficult to understand what Mr McLachlan means by the following sentence —

> "Curdling is still looked on as the signal of milk going bad, and the public should be educated not to drink products which are totally unfit for consumption, simply because there is no clot"

Surely he does not wish to imply, as one might imagine from the context, that pasteurised milk is totally unfit for consumption. And, again, he makes a reference to enzymes which he affirms are destroyed by pasteurisation, and says "there is no justification *for removing them unless some definite advantage* is gained thereby." The definite advantage gained by pasteurisation is that it renders milk safe It seems certain that Marcelin would very much have preferred to partake of a meal which needed four hours for digestion, knowing it to be safe, than one which required half an hour less, but contained dangerous ingredients

Mr McLachlan's statement that—

> "during 'pasteurisation' the lactic acid, but not the putrefactive or sporulating, bacteria are destroyed, with the result that the milk may go bad without curdling if kept for any length of time"

contains an error which was corrected many years ago I refer Mr McLachlan to work done for the Bureau of Animal Industry of the U S Department of Agriculture by S Henry Ayers and William T Johnson, jun, and set forth in a bulletin issued March 24th, 1913 I quote certain passages which are immediately relevant.—

> "An investigation of commercially pasteurised milk in this country showed the presence of high-temperature resisting lactic acid bacteria It was further found that commercially pasteurised milk always soured" (p 10)

The suggestion that reinfection was the explanation of the souring is negatived by subsequent exact laboratory work.

> "The percentage of the acid group is increased by pasteurisation, while the other groups are decreased in their percentage of the total bacteria" (p 59)

> "A qualitative study of the acid group shows that many organisms giving characteristics of the typical lactic acid bacteria survive pasteurisation for 30 minutes at 62 8 C (145° F)" (p 60)

It must be borne in mind that the so-called 'flash" pasteurisation—now universally condemned—was not really pasteurisation at all

Dr Affleck claims that he succeeded in killing the trade of selling sterilised milk in Cheltenham "many years ago" Is it dead to-day? His narrative about the interview with a mother is very amusing indeed He seems *to imply that* that interview killed the trade in sterilised milk In any case sterilisation is not pasteurisation There is one definite statement in his letter, namely —

> "Pasteurised milk has, and will have, the same deplorable results as boiled or sterilised milk, because, and this is the all-important point, *it is cooked*"

May I ask Dr Affleck through your columns to produce evidence of "deplorable results" from the use of boiled, or sterilised milk I do not mean vague statements I do not want reference to laboratory experiments on animals I want proof that such results are found in human beings fed on cooked milk

If Dr Affleck is logical your readers are entitled to expect that he does not boil, or cook, any of his food We are not urged not to cook vegetables or meat or fish or, in fact, any other article of diet but milk Terrible results are not predicted because we bake flour and eat bread Apparently Dr Affleck is unaware that the late Prof Pierre Budin, a pediatrician of world-wide reputation, is on record with the statement that he treated 3000 infants at the Belle Ville Dispensary in Paris, all fed on sterilised —not pasteurised—milk, without seeing a single case of scurvy Eminent pediatricians, particularly in America, are equally emphatic as to the absence of deleterious results of pasteurisation

I want to convince Dr Affleck, and I will suggest that he purchase a pint of milk anywhere, pass it through a white filter paper, and inspect the deposit If he will be at the additional pains of adding a comparable amount of cow-dung to an equal quantity of milk which he has obtained from the udder of a cow free from contamination, and pass that through another filter, and compare the sediment microscopically, he will be satisfied of the nature of the bulk of the contamination If he will plate out some of the deposit he will almost invariably discover *bacilli* of the colon group. If he will inoculate guinea-pigs with milk he will find that from 5 to 10 per cent of the samples will cause tuberculosis in these animals

I hold in my hand at the moment a statement of the result of the examination of a sample of milk purchased this present month It contained 6,774,000 organisms developed at room temperature, in addition to 4 016,000 per c cm developed at blood heat, and colon bacilli were present in 0 000,001 c cm of the milk Dr Charles Hastings, medical officer of health for Toronto, has stated repeatedly in public that it is his conviction that it would be true to write as an epitaph on half of the graves of babies "Killed by dirty milk"

We medical men have a responsibility We may not write, or speak, without adequate information We must disabuse our minds of preconceptions It is hardly satisfactory to permit ourselves to use such phrases as "devitalising or organismal life" I do not know what those words mean Neither do I understand what is meant by the "sthenic value of milk," but I do know that the present supply of milk in this country is dirty and dangerous, and I do know that pasteurised milk has been used for many years, in many places, not only without producing any ill-effects (although interested persons have been anxiously on the look-out to discover them), but that it has caused extraordinary reduction of disease and death among the populations so served

Let me conclude by again asking if we may cook most foods, why may we not cook one particular food?—I am, Sir, yours faithfully,

S G Moore, M D,

Sept 17th, 1926 Medical Officer of Health, Huddersfield

Infectious Disease in England and Wales

(Continued from previous page)

28, continued fever, 1, dysentery, 63; ophthalmia neonatorum, 128, There were no cases of cholera, plague, or typhus fever notified during the week

The notifications of poliomyelitis are still on the increase, cases being reported in numbers from one to four from 18 scattered counties with 17 from Leicestershire (10 from Leicester itself), and 8 from Essex (7 from Orsett R D)

Deaths —In the aggregate of great towns, including London, there were no deaths from small-pox, 4 (0) from enteric fever, 10 (0) from measles, 3 (0) from scarlet fever, 30 (4) from whooping-cough, 20 (5) from diphtheria, 180 (29) from diarrhœa and enteritis under two years, and 12 (1) from influenza The returns from diarrhœa and enteritis show a small rise for the country as a whole and a welcome diminution in London The figures in parentheses are those for London itself, and it is noteworthy that in the week under review there was no death in London either from small-pox, enteric fever, measles or scarlet fever, and only one from influenza

New School Clinic, Birmingham—On Thursday Sept 30th, Sir Humphry Rolleston will open a new school clinic in Sheep-street, Birmingham

Dr Andrew Balfour Director of the London School of Hygiene and Tropical Medicine will next month attend the fiftieth anniversary celebration of Johns Hopkins University Baltimore and will deliver an address at the formal opening of the new building of the School of Hygiene and Public Health of that University.

Plymouth "Penny in the Pound" Scheme—This scheme organised by the Plymouth Voluntary Hospitals Committee has made rapid progress, and it is expected that the total raised in the financial year which expires this month will reach £14 500 Last year it was nearly £11 000 and the year before a little over £6000 There are now close upon 40 000 contributors

Pressure of Emergency Cases—Bolton Infirmary is being greatly embarrassed by the increase in emergency cases On a recent occasion while six operations were being performed six casualty cases were admitted in half an hour each requiring immediate attention During August 356 new casualty cases were treated a considerable proportion of them the result of motoring accidents

Hospitals Welfare Society—Last week Sir George Hume M P chairman of the London County Council, broadcasted an appeal on behalf of the Hospitals Welfare Society Its object is to help five hospitals in South-East London—the Miller, the Seamen's the Blackheath St John's, and the South-Eastern—by weekly house-to-house collections and in six years £25 000 has been raised in this way, about £100 a week is now collected The organisers of the scheme are urging its adoption by hospitals which have no comparable assistance

Papworth Tuberculosis Industrial Settlement—The annual report of Papworth Hall Sanatorium and Industrial Settlement which has just been issued, shows that excellent progress is being made The sanatorium which is a separate unit has treated 1778 cases in ten years and there are now in the institution and the village 559 persons including 90 healthy children of ex-patients No child who was not suffering in a marked degree from tuberculosis before going to live in the colony has shown any sign of infection After the experience of a decade, the medical director Dr P C Varrier-Jones, is confirmed in his belief that settlements of this kind are essential in combating tuberculosis The industries are described as a serious commercial concern, not trading upon sympathy

Royal Institute of Public Health—Problems of Personal and Public Health is the title of a course at the Institute which will begin on Oct 13th with a lecture by Sir William Willcox on Intestinal Infection in Relation to Personal Health and Disease. The four next lectures will be on the following subjects: The Prevention and Treatment of Eczematous Conditions of the Skin of Occupational Origin, by Dr W J O'Donovan, on Oct 20th, Town Planning in Relation to Health, by Prof L P Abercrombie, on Oct 27th; Ventilation in Relation to Health, by Dr H. M. Vernon, on Nov 3rd: and Industrial Psychology Applied to the Home, by Prof Winifred Cullis on Nov 10th. Particulars will be published later of the remaining lectures of the series, which are to be given by Dr R H Miller, Dr C W Saleeby, Dr P C Varrier-Jones, and Lieut-Colonel F E Fremantle All of them will be delivered on Wednesdays at 4 P.M. in the Lecture Hall of the Institute 37, Russell-square, London, W C 1

Maudsley Hospital, Denmark Hill—During and after the second week of October three series of clinical lectures illustrated by cases will be held On Mondays Dr W Moodie will deal with Relations of Mental Disorder to Physical Conditions, on Wednesdays Dr Edward Mapother will deal with Neurotic and Psychotic Syndromes and on Fridays Dr W S Dawson will deal with Mental Symptoms and their Genesis, the hour of all lectures being 2 30 P.M In addition a discussion on cases in the Mental Hospital will be held in the wards every Tuesday at 11 30 A.M and monthly, on the last Friday of each month, at 4 30 P M when a group of patients from one of the L C C mental hospitals will be shown These discussions are open to medical practitioners without fee Posts as clinical assistant can be obtained on application to the Medical Superintendent The course of lectures and practical instruction for the Diploma in Psychological Medicine will be held at the above hospital beginning in January next The lectures and demonstrations are given in series, and either group can be attended separately The fee for the course is ten guineas, or for a single series two guineas, payable to the Fellowship of Medicine, from which copies of the syllabus may be obtained.

Hospitals and the Coal Strike—Hospitals in the coalfields and in a minor degree those in industrial districts are suffering from the long continuance of the deadlock Sunderland Royal Infirmary for example is losing about £300 a week in reduced workmen's subscriptions The subscriptions of employers who contribute on a wages basis are also seriously reduced The loss on workmen's contributions already reaches about £5000

The late Dr A. M McAldowie—After living in retirement at Cheltenham for many years Dr Alexander Morison McAldowie died on Sept. 4th at the age of 74 He was born at Aberdeen and studied at the University there graduating, with highest honours as M B in 1875 and M D in 1879 In the year after qualifying he took up an appointment as resident house physician to the North Staffordshire Infirmary and this he held for four years. Afterwards settling in practice at Stoke-on-Trent, he was in 1889 appointed honorary physician to the Infirmary, and became well known in the midlands, especially for his work on lead poisoning amongst pottery workers He was an important witness at the inquiry held at Stoke by Lord James of Hereford about 25 years ago when he gave an account of experiments made on himself to discover the effects of slow lead absorption Dr McAldowie's keen logical faculty fitted him to be a neurologist and he contributed a number of articles to *Brain* His abilities were recognised by election as F R S Edin and in 1898 he was President of the Staffordshire branch of the British Medical Association But his interests extended far beyond his work He was President of the North Staffordshire Field Club to which he read papers on archæology and natural history and he wrote a book on "The Birds of Staffordshire." On retiring in 1906 he went to live in Gloucestershire and enjoyed similar leisure pursuits During the war he went back to medical work again as honorary surgeon to the Leckhampton Voluntary Aid Detachment Hospital, to which he gave devoted service Dr McAldowie leaves a widow, a son and three daughters

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE HOSTEL, Imperial Hotel, Russell-square, W C

MONDAY Sept 27th—9 P M Prof B J Collingwood will open a Discussion on Hydrogen ion Concentration in Health and Disease

THURSDAY—9 P.M, Dr Andrew Balfour will open a Discussion on The Acclimatisation of the White Man in the Tropics

All medical practitioners cordially invited

HOSPITAL FOR SICK CHILDREN, Great Ormond street, W C

THURSDAY Oct 7th.—4 P M., Dr Cockayne Rickets as it is seen to-day

Mind and Matter The Hon Bertrand Russell F R S Medical Psychology T W Mitchell M D The Development of Philosophy since Kant Prof G Dawes Hicks Ph D Litt D The Problems of Philosophy The Hon Bertrand Russell Psychology: Prof C W Valentine D Phil.

Full syllabus on application to The Director of the Institute.

REACTION TO BLOOD TRANSFUSION

To the Editor of The Lancet

Sir,—Your leading article of Sept 11th refers to Dr C A Doan's work on incompatibility in blood transfusion My personal experience of transfusions is limited to 63 cases (mostly those of Mr Gordon-Taylor) carried out during the past 18 months at the Middlesex Hospital In every case I performed a cross-agglutination test between the donor's corpuscles and patient's serum, the former having first been shown to belong to the same group as the recipient, or to be a member of the fourth group In five cases I was not satisfied as to the compatibility of the bloods, since agglutination of the donor's corpuscles occurred, but always after an appreciable interval of time which varied from 3–10 minutes, and never so markedly as a control test performed with the recipient's serum and an obviously incompatible donor. These cases I referred to Dr S L Baker for the performance of a microscopic agglutination test Two donors he bid me discard, but permitted the use of the other three Thus it would appear that approximately 3 per cent of the donors proved unsuitable when tested "directly," notwithstanding their belonging either to the same groups as their corresponding recipients or being members of Group IV.

The conclusion is identical with your own—it is not wise to undertake a transfusion in the absence of a direct agglutination test The point is of great practical importance and sometimes leads to difficulty in finding a suitable donor On one occasion I tested eight donors, all of the patients' group (IV), before finding one who gave a negative cross-agglutination test To my mind there is little doubt that more than four groups exist, but whether we have, at the present time, a convenient and rapid means of differentiating them is another matter.

I am, Sir, yours faithfully,

Frederick W Roques, M B , B Ch ,
Senior Demonstrator in Anatomy, late House Surgeon,
Sept 15th, 1926 Middlesex Hospital

Medical News.

Epsom College —The Council of the College is about to award one of the Leopold Salomons Entrance Scholarships of £50 per annum which were established "as a slight recognition of the splendid work of the medical profession carried on during the war" Candidates must be sons of legally qualified members of the medical profession who are unable to enter Epsom College without the help of this scholarship Only those boys can become candidates who were 11 years of age and under 14 on Jan 1st last, and can show a standard of education adequate for their age Their general character and physical condition, as well as their mental capacity, must be satisfactory to the Council Applications must be received not later than the morning of Oct 6th —The Council will also shortly award a special St Anne's Home Scholarship of £52 a year, tenable for about five years, to the orphan daughter of a medical man who was in independent practice in England or Wales for not less than five years Only those are eligible as candidates who were fully 10 years of age and not over 12 on May 1st last Forms of application and full particulars of both these scholarships may be had from the Secretary of Epsom College, 49, Bedford-square, London, W C 1

London Medical Exhibition —Daily from Oct 4th to 8th, from noon until 6 30 P M , the London Medical Exhibition will be open to members of the medical profession at the Central Hall, Westminster These annual exhibitions were started in 1905 and this will be the largest yet held The most recent applications of science to practice will be on view, and a very large number of devices and preparations for treatment and diagnosis are to be shown There is usually a big attendance of doctors and a reception-room, a tea-room, and light refreshments are provided to give visitors a chance of seeing their friends Invitation cards will be sent to every member of the profession residing within a 30-mile radius of the hall Those who have not received cards can get them on application to the Secretary, the London Medical Exhibition, 1[illegible]-200, Bishopsgate, London, E C , or at the Central Hall during the exhibition week

Hunterian Society —The coming session will begin with a dinner meeting at Simpson's Restaurant, Cheapside, on Monday, Oct 18th, at 7 30 P M., when Mr. Mortimer Woolf will give a presidential address on Pain. Later meetings will be devoted to discussions on Medicine and the Press, the Nervous Child, and other subjects, the Hunterian Lecture being delivered on Jan. 17th by Dr J M T Finney, of Baltimore, who has chosen to speak on the Influence of John Hunter on American Surgery The annual dinner of the society will be held at the Hotel Victoria on Feb 10th.

Course in Radiology and Electrology in Paris —On Oct 5th, and the following Tuesdays, at 9 A M , at the Beaujon Hospital, Dr Aubourg and Dr Joly will give practical demonstrations of deep X Ray Therapy in the Treatment of Tumours On Oct 8th, and the following Fridays, at 9 A M , in Dr Aubourg's Electrical Laboratory at the Beaujon Hospital, Dr Vignal and Dr Quivy will give practical demonstrations of Electrical Diagnosis and Treatment On request demonstrations will be given in English, and no fee will be charged

Opening of the Medical Schools —The following arrangements have been made in connexion with the opening of London medical schools —

St Bartholomew's Hospital —Old students' annual dinner, Friday, Oct 1st, at 7 for 7 30 P M in the Great Hall of the Hospital Chairman Mr W T Holmes Spicer

St George's Hospital —Old students' annual dinner, Friday, Oct 1st, at 7 15 for 7 45 P M at the Hyde Park Hotel, Knightsbridge Chairman Captain C C Craig, M P Inaugural address, by Dr Graham Little, on Oct 1st, at 3 P M , in the board room

Guy's Hospital —Dr John Fawcett will distribute the prizes for the past year on Tuesday, Oct 5th, at 3 P M , and afterwards give an address to the students

King's College Hospital —Introductory address by Sir Humphry Rolleston, Friday, Oct 1st, at 2 30 P M , at the Medical School, Denmark Hill Annual dinner of past and present students on the same day at 7 for 7 30 P M at the Criterion Restaurant, Piccadilly Chairman Dr F Jacob

London (R F H) School of Medicine for Women —Introductory address by Sir Walter Fletcher, Friday, Oct 1st, at 3 30 P M., at the Medical School

St Mary's Hospital —Annual dinner of past and present students, Monday, Oct 4th, at 7 for 7 30 P M , at the Connaught Rooms, Great Queen-street, W C

Middlesex Hospital —Introductory address by Prof Thomas Yeates, Friday, Oct 1st, at 3 P M , at the Queen's Hall, Langham-place, followed by prize distribution by the Archbishop of Canterbury Annual dinner of past and present students of the school on the same day at 7 30 P M at the Savoy Hotel Chairman Mr Victor Bonney

Westminster Hospital —Inaugural address by Sir Archibald Garrod, Friday, Oct 1st, at 3 P M , in the board room

Donations and Bequests —Miss Lucy Gordon Roberts, of Brockenhurst, Kent, besides many other bequests, left £1500 to the People's Dispensary for Sick Animals of the Poor, £600 to King Edward's Hospital Fund, and £400 to the Battersea General Hospital —Mr James John Chiswell, of Kingsway, Holborn, W C , left on the death of his wife £1000 to Guy's Hospital and £500 each to Dr. Barnardo's Homes and St. Dunstan's Hostel for the Blind —Miss Dora Cruddas, of Haughton Castle, Northumberland, bequeathed £20,000 to St John's College, Durham, £3000 to Dr Barnardo's Homes, and £2000 each to several institutions, including the Royal Victoria Infirmary, Newcastle-on-Tyne —Mr John Ditchfield, of St. Anne's-on the Sea, and Manchester, left £250 to St Mary's Hospitals, Manchester, and £100 each to the Manchester Royal Infirmary and Ancoats Hospital, Manchester —Mr John Alexander Hodgman, veterinary surgeon, Barnsley, left £1000 to the Becket Hospital and Dispensary to endow a bed —Mrs. Maria Beard, of the Mount, Ashbourne, Derbyshire, left £2000 each to the Oldham Royal Infirmary, Dr Barnardo's Homes, and the Blinded Soldiers' and Sailors' After care Organisation, £1000 to the Derby Infirmary, and £300 to the Victoria Memorial College Hospital, Ashbourne —Mrs. Louisa Thomson-Price, of Hampstead, N W , left subject to a life interest £1000 to endow a bed in the Elizabeth Garrett Anderson Hospital, Euston-road —Mr Thomas Harry Rose, J P , of Oxford, left £1000 to the Radcliffe Infirmary and County Hospital, Oxford, and £350 to the Oxford Eye Hospital —Dame Mary Anne Anderson, of Beechwood, Murrayfield, Edinburgh, widow of Sir George Anderson, left the property Beechwood and £5000 to the Edinburgh Royal Infirmary, £5000 to the Senatus Academicus of the University of Edinburgh, and £2000 to the Royal Infirmary, Dundee —Lord Rothermere, honorary treasurer of the "Fleet Street Week" for St Bartholomew's Hospital, has given £5000 to the fund

NEW SCHOOL CLINIC, BIRMINGHAM —On Thursday Sept 30th, Sir Humphry Rolleston will open a new school clinic in Sheep-street, Birmingham

Dr Andrew Balfour Director of the London School of Hygiene and Tropical Medicine will, next month, attend the fiftieth anniversary celebration of Johns Hopkins University, Baltimore, and will deliver an address at the formal opening of the new building of the School of Hygiene and Public Health of that University

PLYMOUTH "PENNY IN THE POUND" SCHEME —This scheme, organised by the Plymouth Voluntary Hospitals Committee, has made rapid progress, and it is expected that the total raised in the financial year which expires this month will reach £14 500 Last year it was nearly £11,000, and the year before a little over £6000 There are now close upon 40,000 contributors

PRESSURE OF EMERGENCY CASES —Bolton Infirmary is being greatly embarrassed by the increase in emergency cases On a recent occasion, while six operations were being performed six casualty cases were admitted in half an hour, each requiring immediate attention During August 356 new casualty cases were treated a considerable proportion of them the result of motoring accidents

HOSPITALS WELFARE SOCIETY —Last week Sir George Hume M P chairman of the London County Council, broadcasted an appeal on behalf of the Hospitals Welfare Society Its object is to help five hospitals in South-East London—the Miller, the Seamen's, the Blackheath St John s, and the South-Eastern—by weekly house-to-house collections, and in six years £25,000 has been raised in this way, about £100 a week is now collected The organisers of the scheme are urging its adoption by hospitals which have no comparable assistance

PAPWORTH TUBERCULOSIS INDUSTRIAL SETTLEMENT —The annual report of Papworth Hall Sanatorium and Industrial Settlement, which has just been issued, shows that excellent progress is being made The sanatorium, which is a separate unit has treated 1778 cases in ten years, and there are now in the institution and the village 559 persons including 90 healthy children of ex-patients No child who was not suffering in a marked degree from tuberculosis before going to live in the colony has shown any sign of infection After the experience of a decade, the medical director, Dr P C Varrier-Jones, is confirmed in his belief that settlements of this kind are essential in combating tuberculosis The industries are described as a serious commercial concern, not trading upon sympathy

ROYAL INSTITUTE OF PUBLIC HEALTH —Problems of Personal and Public Health is the title of a course at the Institute which will begin on Oct 13th with a lecture by Sir William Willcox on Intestinal Infection in Relation to Personal Health and Disease The four next lectures will be on the following subjects · The Prevention and Treatment of Eczematous Conditions of the Skin of Occupational Origin, by Dr W J O'Donovan, on Oct 20th , Town Planning in Relation to Health, by Prof L P Abercrombie, on Oct 27th ; Ventilation in Relation to Health, by Dr H. M. Vernon, on Nov 3rd , and Industrial Psychology Applied to the Home, by Prof Winifred Cullis, on Nov 10th. Particulars will be published later of the remaining lectures of the series, which are to be given by Dr R. H. Miller, Dr C W Saleeby, Dr P C Varrier-Jones, and Lieut - Colonel F E Fremantle All of them will be delivered on Wednesdays at 4 P.M. in the Lecture Hall of the Institute, 37, Russell-square, London, W C 1

MAUDSLEY HOSPITAL, DENMARK HILL —During and after the second week of October three series of clinical lectures illustrated by cases will be held On Mondays Dr W Moodie will deal with Relations of Mental Disorder to Physical Conditions ; on Wednesdays Dr Edward Mapother will deal with Neurotic and Psychotic Syndromes , and on Fridays Dr W S Dawson will deal with Mental Symptoms and their Genesis, the hour of all lectures being 2.30 P.M. In addition a discussion on cases in the Mental Hospital will be held in the wards every Tuesday at 11 30 A.M and monthly, on the last Friday of each month, at 4 30 P M when a group of patients from one of the L C C mental hospitals will be shown. These discussions are open to medical practitioners without fee Posts as clinical assistant can be obtained on application to the Medical Superintendent The course of lectures and practical instruction for the Diploma in Psychological Medicine will be held at the above hospital beginning in January next The lectures and demonstrations are given in series, and either group can be attended separately The fee for the course is ten guineas, or for a single series two guineas, payable to the Fellowship of Medicine, from which copies of the syllabus may be obtained.

HOSPITALS AND THE COAL STRIKE —Hospitals in the coalfields and in a minor degree those in industrial districts are suffering from the long continuance of the deadlock Sunderland Royal Infirmary for example, is losing about £300 a week in reduced workmen's subscriptions The subscriptions of employers who contribute on a wages basis are also seriously reduced The loss on workmen's contributions already reaches about £5000

THE LATE DR A M MCALDOWIE —After living in retirement at Cheltenham for many years Dr Alexander Morison McAldowie died on Sept 4th at the age of 74 He was born at Aberdeen and studied at the University there graduating, with highest honours as M B in 1875 and M D in 1879 In the year after qualifying he took up an appointment as resident house physician to the North Staffordshire Infirmary and this he held for four years Afterwards settling in practice at Stoke-on-Trent, he was in 1889 appointed honorary physician to the Infirmary, and became well known in the midlands especially for his work on lead poisoning amongst pottery workers He was an important witness at the inquiry held at Stoke by Lord James of Hereford about 25 years ago when he gave an account of experiments made on himself to discover the effects of slow lead absorption Dr McAldowie's keen logical faculty fitted him to be a neurologist, and he contributed a number of articles to *Brain* His abilities were recognised by election as F R S Edin , and in 1898 he was President of the Staffordshire branch of the British Medical Association But his interests extended far beyond his work He was President of the North Staffordshire Field Club to which he read papers on archæology and natural history, and he wrote a book on " The Birds of Staffordshire " On retiring in 1906 he went to live in Gloucestershire and enjoyed similar leisure pursuits During the war he went back to medical work again as honorary surgeon to the Leckhampton Voluntary Aid Detachment Hospital, to which he gave devoted service Dr McAldowie leaves a widow, a son and three daughters

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST GRADUATE HOSTEL, Imperial Hotel, Russell-square, W C
MONDAY Sept 27th.—9 P.M., Prof B J Collingwood will open a Discussion on Hydrogen-ion Concentration in Health and Disease
THURSDAY —9 P M , Dr Andrew Balfour will open a Discussion on The Acclimatisation of the White Man in the Tropics
All medical practitioners cordially invited

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W C
THURSDAY Oct 7th.—4 P M , Dr Cockayne Rickets as it is seen to-day

ANCOATS HOSPITAL POST-GRADUATE COURSE
THURSDAY Sept 30th —4 15 P.M., Mr Harry Platt Treatment of Common Injuries Sprains and Minor Injuries of Joints, Muscles and Tendons

ST MARGARET S HOSPITAL FOR WOMEN, Acomb street, Whitworth Park, Manchester
WEDNESDAY Sept 22nd.—4 P M President's Address Social Meeting Mr A C Magian The Uses and Abuses of Curettage

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSES
TUESDAY Sept 28th.—4 15 P M , Mr C Roberts The After-treatment of Surgical Cases
FRIDAY —4 15 P.M , Dr R. Veitch Clark General Survey of Cancer Incidence

BRITISH INSTITUTE OF PHILOSOPHICAL STUDIES, 88, Kingsway, London W C
A course of Lectures on the following subjects will begin on Oct 4th —
Mind and Matter The Hon Bertrand Russell F R.S Medical Psychology T W Mitchell M D The Development of Philosophy since Kant Prof G Dawes Hicks Ph D Litt D The Problems of Philosophy The Hon Bertrand Russell. Psychology Prof C W Valentine D Phil.
Full syllabus on application to The Director of the Institute

Appointments.

Cunningham, R. G , M B , Ch B Edin , has been appointed one of the Medical Referees under the Workmen's Compensation Act, for the Districts of the Consett, Durham, Seaham Harbour, and Sunderland County Courts

Owen, D Rhydwyn, M B , B Ch , B Sc , Assistant Medical Officer, Glamorgan County Mental Hospital, Bridgend

Vacancies.

For further information refer to the advertisement columns

Belgrave Hospital for Children 1, Clapham road S W —H S and Asst H P At rate of £100 each

Birmingham, Highbury Group of Hospitals —H P £350

Cardiff City Mental Hospital, Whitchurch —Sen Asst M O £550

Cardiff Royal Infirmary —Ophth H S At rate of £50

Croydon General Hospital —Pathologist and Bacteriologist (Part-time)

Dominica, British West Indies —M O H £1000

Doncaster Royal Infirmary and Dispensary —Third H S At rate of £150

Dublin, St Vincent's Hospital —Asst S to Out patient Dept

Grosvenor Hospital for Women, Vincent-square, S W —Hon Reg

Hospital for Consumption and Diseases of the Chest, Brompton, S W —Phys Also Asst Res M O At rate of £150

Hospital for Epilepsy and Paralysis, Maida Vale W —Res M O and H P At rate of £150 and £100 respectively

Hospital for Sick Children, Great Ormond street, W C —H S , H P , and Asst Cas O Each at rate of £50

Ilkeston Borough —M O H and School M O £800

London Hospital Dental School, E —Asst Dental Anæsthetist £25

Miller General Hospital for South-East London, Greenwich road, S E —H P £125

Norwich City —Temp Asst School M.O £11 11*s* weekly

Paddington Green Children's Hospital, W —H P and H S Each £150

Prince of Wales's General Hospital, Tottenham, N —Two H S 's and H P Each at rate of £120 Also Jun H S and Jun H P At rate of £90 each

Queen's Hospital for Children, Hackney road, E —P in charge of Skin Dept

Royal National Orthopædic Hospital, 234, Great Portland street, W Surg Reg £100

St John's Hospital, Lewisham, S E —Res Cas O At rate of £100

South London Hospital for Women, South Side, Clapham Common, S W —Clin Asst £1 1*s* per attendance

Swansea Hospital —H P £150

Willesden General Hospital, Harlesden road, N W —Res H S and Non Res Cas O Each at rate of £100

Births, Marriages, and Deaths.

BIRTHS.

McKendrick —On Sept 16th, at Sanquhar, Blackwood, the wife of Wm McKendrick,, M B , Ch B , of a son

Moore —On Sept 13th, at Mundens, Malmesbury, the wife of Reginald M Moore, M B , of a daughter

Walker —On Sept 14th, at a nursing home, Aberdeen, the wife of Edward R C Walker, M B , Ch B , of a son

Wall.—On Sept 17th, at the Victoria Nursing Home, Shanghai, China, the wife of A D Wall, M B , F R C S , of a daughter

MARRIAGES

Elkington—Springett —On Sept 1st , at Ringmer, Sussex, Capt Eric H W Elkington, R A M C , to Margaret Evelyn Springett, younger daughter of the late Arthur R and Mrs Springett, of Montreal, and granddaughter of the late Sir Alexander I Galt, first High Commissioner of Canada

Hislop—Cowan On Sept 13th, at Rosehall Church, Edinburgh Major J H Hislop, M C , I M S , to Jenny, daughter of Sir John Cowan, LL D , and Lady Cowan, Edinburgh

Lloyd—Buley —On Sept 14th, at the Church of the Oratory, Brompton-road, London, Neville Langdon Lloyd, M B , M R C P , to Nora, daughter of Mr and Mrs A G Buley, of Onslow near Guildford

McCallin—Charlton —On Sept 14th, at All Saints' Church, Whitstable, William McCallin, M D , M R C P , and Barrister-at-Law, Inner Temple, of Southampton, to Violet Mary, only daughter of Mr and Mrs C R Charlton, of Folkestone

McCormick—Irons —On Sept 14th at Shandon United Free Church, Edward William McCormick M B , Ch B to Moyra Hope, youngest daughter of Mr and Mrs J J Irons, of Chapelburn, Shandon, Dumbartonshire

DEATHS

Rowe —On Sept 17th, at Shottendane, Margate, Arthur Walton Rowe, M B , M R C S , F G S , &c , late Major, R A M C

Smith —On Sept 19th, Walter Richard Hugh Smith, M D , Senior Assistant Medical Officer, Salop Mental Hospital, Shrewsbury

N B —A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

Notes, Comments, and Abstracts.

WHAT IS A MENTAL ILLNESS?*

By Noel H M Burke, M R C S Eng , D P M Lond.

(Concluded from p 631)

The Medical Point of View

Paranoia —Just as we can imagine that a man is distinctly more mental than an oyster, so we can imagine no more obviously mental illness than paranoia The most ardent toxic-absorptionist could hardly regard a well-developed paranoiac state as anything but purely mental The subject, or patient, is perfectly well in body while alive, there is no morbid change to be found when he is dead His trouble is that he cannot reason reasonably on certain subjects, but persistently forms erroneous judgments and backs them with emotional belief Except within the field of the delusional system he is well Within it he is most certainly ill, yet one cannot explain by any neural or other physical theory his fondness for projecting his own ideas on to others or for persisting in the most irrational of false beliefs So much for a quite superficial review A deeper investigation by any sort of psychological approach makes the mental quality more plain by gradually unfolding the mechanism and causation of the illness The kind of picture obtained is of a man whose achievement has never approached to his ambition, and who has compensated for his failure by giving himself success in phantasy and by believing his phantasy to be reality This he has done time after time, and the further you look into his life the further do you trace the process But the psycho-analysts, who seem to be the only people who are doing thorough and exhaustive research in the psychological side of these matters, tell us that there is more to be known. They say they have reduced this disease to its simplest and most fundamental constituents, and that it depends on a failure of libido development at the later anal-sadistic stage, where the individual has passed a little beyond narcissism, but has not achieved to full object love Whether we go the whole way with the Freudians or are satisfied with a more modest psychological view, we can feel confident that such a disease as paranoia, whose only symptoms are mental ones and whose only explanation or presently known causation is mental, should be classed as a mental illness within the terms of the definition

Compulsion and Obsessional States —Another group of symptoms that represents an illness of equally mental quality is that of the compulsion and obsessional states One man was miserable whenever the number 13 came in contact with him, even in so subtle a form as a morning greeting so phrased that it contained 13 letters He adopted a device of adding some word so that the danger of 13-ness was warded off Another was compelled to read murder news in the daily papers though it frightened him to do so Another, if he read or thought of anyone in any kind of trouble or distress, had to read or think again, being sure that he did so with his mind attuned in kindliness and sympathy towards the sufferer There is a kind of neural explanation for this and similar disorders of conduct and emotion—namely, the conditional reflex This substituted stimulus reaction is, however, merely the neural mechanism of a part of habit formation It does not explain the whole of habit formation in the human being, and it does not appear to meet fully the case of the widespread psychological substitution through several stages that is found in the obsessional neurosis There does, however, seem to be a satisfactory explanation of the symptoms by the psychological mechanisms of repression and displacement of the affect from the repressed conflict situation to other situations which can be treated as substitutes for it The work of the analytic school seems to show a basis in failure in early infantile development, the conflict depending on love and hate towards the same object There is no morbid anatomy of this disorder, and experience shows that the best chance of improvement lies in a course of treatment by psychological methods

Dementia Præcox —We now come to a more doubtful condition, dementia præcox It is possible to argue that this is not a disease entity, it covers so wide a field with so varied a range of appearances, and its results are so uncertain On the whole, however, it is usually accepted as a fairly satisfactory entity with large subtypes It is more difficult to decide whether it should be classed as a mental or a physical disease On the one hand there is a physical pathology and it has to be accounted for, on the other hand, there is a psychopathology, and this, too, must be considered For the physical theory one must consider the presence of immature cortical cells, of degenerated cortical cells and of areas of gliosis, that have been described by various observers Again, there are the regressive atrophic changes in the cells of the testes and other endocrine glands which have been demonstrated by Mott and his co-workers All these and other evidences that have been found point to a structural defect, and certainly some cases of dementia præcox seem to merge into the group of mental defectives Against the physical theory one finds that at the other end of the series of cases in this category the condition merges into the paranoid class, and in fact there is a fairly complete series of types bridging the gap between the purely physical and purely mental extremes. The psychic symptoms of negativism, impulsiveness, tendency to mannerisms and to phantasy, and general failure to meet reality are fairly general and typical The analytic view, as shown in Abraham's scheme, claims that dementia præcox dates to breakdown of libido development at the earlier oral (sucking) stage, at the level of objectless auto-erotism It is difficult to adduce evidence based on results of treatment. A number of cases that appear to be developing into dementia præcox come for treatment and seem to be arrested We all think we have had this experience, but it cannot be proved, for none can say with scientific accuracy what would have been The cases of fuller development get very little chance of thorough psychological treatment. They go where these things are not done Can one come to any conclusion about this disease? It seems that we do not know enough about it yet The evidence is conflicting and we may believe but we cannot yet know.

Manic Depressive.—Another series of cases comes under the group of manic-depressive psychosis, and here again there is room for doubt. In each phase there is bodily illness In the depressed phase there are a number of symptoms suggestive of a hypothyroidism and another set resembling the Parkinsonian syndrome. In the maniacal phase the patient is thin anæmic, and below normal but shows hyperæsthesia and motor excitement instead of the reverse as in the depressive period Many have concluded that this is an organic disease depending on some disturbance of blood pressure or of endocrine balance or on toxic absorption. Even Stoddart, in his 1921 edition, elaborates a theory of intraneuronic intoxication which provides an ingenious physical explanation for the various symptoms of the disorder, but does not satisfactorily account for the whole pattern of the illness with its typical rhythms of alternation. He modifies this however by proceeding to give the psycho-analytic view of the disease as depending on infantile masochistic attitudes with phases of self-reproach, alternating with periods of elation at the winning of freedom from the hated object of the patient s love. It may be that the next edition will show a more decided bias to the psychical view

Acute Confusional States—Under the general heading of acute confusional insanity one can group the toxic and exhaustion insanities including such alcoholic conditions as physiological inebriation and delirium tremens. Here we deal with a frankly physical condition for which there is no real psychological foundation nor any but physical treatment. One must bear in mind that in, at any rate, one group—the puerperal—there may be a strong mental cause at work, as well as the physical, and we must return presently to the general consideration of the mental symptoms of this physical state.

General Paralysis—The definition of general paralysis of the insane is "a chronic progressive disease of the cerebral cortex, associated with psychic and motor disturbances leading to dementia and paralysis' Of all diseases having mental symptoms this has the largest list of physical signs and of pathological changes and it is quite clearly a bodily disease The whole of the active treatment is based on this view and consists of devices to destroy the spirochæte and its toxins Beyond this nothing is done but to protect the patient, so far as is possible, while passively waiting for the inevitable progress of the disease.

Mental Symptoms of Organic States

We can now consider the mental aspect of these and other organic states In the toxic group there is mainly confusion rather than emotional disturbance. The patient cannot understand and think clearly he cannot even perceive clearly He has clouding of consciousness, fleeting delusions, and always shows hallucinations He may be in any state between delirium and stupor

There is no systematisation of the mental state that can be regarded as peculiar to this physical disorder Some resemble the depressed or exalted periods of manic depressive The katatonic variety is like the katatonia of dementia præcox In the cases associated with childbirth Cole describes three periods of onset with differing mental pictures. The woman who falls ill during pregnancy tends to show a condition resembling manic depressive. If she develops her trouble shortly after the birth of the child she shows a depressed and melancholic picture, while the case developing at or about parturition is likely to be a katatonic or an ordinary acute confusional.

The mental symptoms of general paralysis are summed up by Porter Phillips as the following Early change of personality and temperament irritability and restlessness, absent-minded, inattentive, preoccupied, loss of recent memory, impaired higher functions, and reasoning &c In general there may be exaltation, mania melancholy, delusion, or alternations between these. Beyond this one sees a progressive dissolution down to second childishness and mere oblivion. The mental picture is diffuse and ill-systematised, and lacks the definition and completeness of pattern that one finds in the purely mental illnesses

After all, the diagnosis of G P I. depends on the finding of varied mental derangements that do not conform to the pattern of any pure psychosis and on their alliance with certain definite physical signs The euphoria that is seen very early in this illness is, in a way, typical but not absolutely so for there is something very similar in disseminated sclerosis, which has never been called a mental illness It may be due, in both cases, to the presence of toxins in the cerebro-spinal fluid and their effects on the same areas of brain tissue. Some cases of encephalitis lethargica are reported to have begun with a feeling of extreme well-being which may perhaps have a similar explanation.

Gross Cerebral Lesions—If we turn to the mental disturbances following other gross brain lesions such as tumours, thrombosis and softening, and cortical atrophy we find a rather similar picture of diffuse ill-organised changes with a progressive and general deterioration. When there is systematisation of the mental change it resembles one or other of the accepted psychotic or psychoneurotic diseases. For this resemblance it is possible to find an explanation. It is suggested that interference with physiological function in the higher cortical regions of the brain interferes with that which in phys ological language is inhibition, and in psychological language is repression. If this be so, then we must take it that with a damaged brain cortex we may be unable to maintain control over such fundamental desires as we may have mastered previously and they will—by *relative* increase of strength though not by actual increase—become manifest in the form of the appropriate mental illness

This explanation, if a true one, opens up two lines of thought. In the first place it would seem to show, what may be true, that there are very few individual forms of mental illness that are possible to us Stoddart, in his classification gives about ten under three main groups of neuroses, psychoneuroses, and psychoses It may be that, as time goes on, these ten will be reduced to about half that number In the second place we are thrown up against the problem of the relation between cortical function, which belongs to physiology, and repression, which belongs to psychology The problem is beyond the limits of this paper

Summary of Medical Evidence

Summing up what we have noted in this survey of diseases showing mental changes, we come to a view of mental illness in which the medical outlook corresponds very closely with the psychological and with the philosophical.

It appears that we may devise a kind of medical philosophy in which disease process will be regarded as, in a way, a unity having manifestations that vary with the precise cause at work in each case, and with the location of the chief disorder At the one end of a long series there is purely physical disease with no mental change at all or, as we saw earlier none that has importance. From here we move through a gradation of differences, through physical disease showing mental symptoms, and mental disease showing physical symptoms, to diseases that are purely mental and have no physical aspect or, at any rate, none that is practically important. By way of example one might consider at one end a broken leg, next paralytic dementia or G P I next anxiety neurosis, and lastly paranoia. In the middle one would have to put manic-depressive and dementia præcox as being still uncertain in ætiology They both have the appearance of being very mental in quality, but they also are under suspicion of being very physical as well.

Epilepsy—We can illustrate the whole series by a group of conditions that have all, at one time or another, been classed as epilepsy Epilepsy, of course, means only "the falling sickness" and the sick people who fall in this peculiar way can be ranged in a line having at one end those with gross brain lesion and resulting Jacksonian fits, and at the other those with no known or discoverable physical lesion but definitely mental fits—the hysterical fit cases It is not possible to draw a line between, so as to separate the purely organic from the purely functional The Jacksonian attack is not a necessary sequelæ of brain lesion, an apparently mental type of fit may be determined by brain lesion, a Jacksonian may be imitated by attacks due to emotional disturbance, and so on In the middle, somewhere, is the diminishing group of true or idiopathic epilepsy The physical school claims it, and now the psychological school claims it as representing cases of undeveloped, somewhat defectively made people of peculiar personality who are sexually infantile in mind and express the effects of this attitude in their attacks Allied to this series are asthmatics and sufferers from migraine

What at present seems to underly the whole is a spasmophilic condition of unknown nature, perhaps functional, whose existence enables its possessors to have fits when stimulated by the appropriate method This in some cases is a mechanical injury, in some a toxæmia, and in others an emotional situation

The Social Point of View

We can deal very briefly with the social attitude to the question, "What is a mental illness?" Society is not at present concerned with problems of ætiology or of scientific accuracy Up to recent times its only concern was its own comfort From this it followed that any person who was so disordered in his behaviour as to be too great a nuisance was put where he no longer bothered More recently there has grown up some care for the patient himself, as shown by the idea of protecting him and making his lot more comfortable The social point of view to-day is therefore that a person is insane if he needs care and control for the protection of others *or* of himself

There are signs, however, of the growth of a still wider and more reasoning view of mental illness as a social problem Public opinion is turning towards recognition of the very great number of citizens who suffer from some form of mental illness, to the hardships they consequently undergo, and to the loss they cause to the community as expensive and inefficient members It is therefore beginning to look for means of lessening the problem by prevention, and we have evidence of this attitude in the insistence, by almost every witness before the recent Royal Commission, on the necessity of the provision of better facilities for early treatment of mental illness

With this view we can all agree, and it will do no harm if we decide at an early date what a mental illness really is

LIFTING OF HEAVY WEIGHTS

THE Woollen and Worsted Textiles (Lifting of Heavy Weights) Regulations, 1925, apply only to weights lifted by one person—i e, they do not fix any maximum limit for weights lifted jointly by two or more workers The Home Secretary proposes to amend them to secure that where two or more workers are concerned, the total weight, when divided by the number of persons employed, shall not exceed the maximum limit allowed for the individual worker, or, where the workers belong to different categories, the maximum limit fixed for the worker in the lowest category concerned He hopes that this proposal will be accepted without question, but if any person desires the Regulations to be further considered, he should lodge an objection at the Home office in proper form not later than Oct 20th

FLY PREVENTION IN BERMUDA

THE group of coral islands in mid-Atlantic, known as Bermuda, is so densely populated (600 to the square mile) that intensive cultivation is needed for the fields which lie on a bed of aeolian limestone Motor transport being forbidden, the horse-population of 150 to the square mile provides a good supply of manure and on it in a climate so moist and warm, flies thrive Enteric fever is endemic, so that fly prevention is of the first importance The manure cannot be burned for economic reasons, spreading was tried, but abandoned, for in that windswept spot the ambient air became filled with horse litter, spraying with fly-deterrents killed only the larvæ near the surface of the dumps Major E B Allnutt[1] remembered the advice given by Lieut E Baber, South African M C (THE LANCET, 1918, i, 471), to pack the manure firmly together each day in a cell with impermeable walls and floor so as to secure a temperature of decomposition high enough to destroy the developing fly larvæ Storage was done in pairs of cement-faced cells, 5 ft by 5 ft by 2½ ft wide, just large enough to take the manure of a horse for ten days The larvæ, as they hatched out, finding the centre of the mass too hot to hold them, moved to the cooler periphery, whence they were raked off and pushed into the hot centre of the mass The cement floor extending a foot forward of the heap ends in a water channel containing 2 in of weak cresol, into which the larvæ which attempt to reach the cool earth outside in order to pupate, fall and are drowned The gutter is finished on the outer side with an inverted J moulding which the larvæ cannot pass, indeed, Major Allnutt arranged a similar overhanging edge to each of the walls of these cells, so that escape was impossible in any direction and fly multiplication ceases When one cell is filled, its contents stand for ten days until all the larvæ are dead and the compost unattractive to flies, when it can be safely laid on the fields. Meanwhile the other cell of the pair is put into use Simple as is the mechanism and successful in his hands, Major Allnutt reminds those who would follow him that the control of flies requires constant supervision and unceasing labour

CHRISTCHURCH HOSPITAL, NEW ZEALAND

Dr P Clennell Fenwick has published a well written and admirably illustrated "Historical and Descriptive Sketch" of this hospital, of which he is consulting surgeon, accompanied by a separate "Review" of the radium and deep therapy department The hospital, which was established in 1862, stands upon a beautiful, but inadequate riverside site In its early days on a voluntary basis it had to contend with serious financial difficulties, but eventually it was supported partly from the rates and partly by a Government subsidy, and there have, in addition, been substantial private benefactions Thus a large ward was built and endowed by a Polish Jew settler in the dominion, while a lady gave a large block for chronic cases, and another benefactor the radium and deep therapy department, which possesses £8000 worth of radium and a Victor deep X ray machine which cost £4000 In the first 18 months more than 500 cases were treated, and the after-history of the patients is being carefully watched Also there is a large venereal disease department, and by means of an affiliated society the hospital organises health propaganda. Dr Fenwick is strongly in favour of provision for private paying patients The hospital controls more than a dozen provincial hospitals, sanatoria, homes, and orphanages

A WANDERING TUMOUR.

To the Editor of THE LANCET

SIR,—I should like to get an explanation of a case I record below

I was shown a child 1 year and 6 months old The history was that the child had suffered from no mentionable injury, but that a tumour was found in the ischiorectal region in May, 1926, when a medical man was consulted who prescribed an ointment for external use In June it remained as it was, so a specialist in the diseases of children was consulted who gave similar treatment In July the tumour had disappeared, to the credit of the specialist's ointment, but a T-shaped glandular mass was felt in the iliovesical region of the abdomen The same specialist was consulted again, and advised removal of the mass by operation or the use of the same ointment The parents inquired if an X ray photo would elucidate the matter, but the specialist showed no special inclination for it In August the mass disappeared again, to the credit of the specialist's ointment, but I found that a mass had formed in the postero lateral part of the right thigh With the consent of the father, I removed the tumour under local anæsthesia, and found, as I expected, a needle The father immediately declared that he had all the time considered the tumour to have contained a foreign body Would it be right to say that the child had swallowed the needle some time before May?

I am, Sir, yours faithfully,
G L DESHMUKH
Bombay, India, Sept 1st, 1926

THE BIRTH OF UNIVERSITY COLLEGE

A SMALL book[1] by Sir Philip Magnus reproduces the centenary address which he gave at University College last April He did well in that address to recall the difficulties and obstacles which University College had to meet at its inception On the face of it the opposers of the scheme had some good grounds of disapproval The venture had a commercial appearance, the *Quarterly Review* described it as "a joint stock speculation in education of which the Dissenters and their friends were the principal shareholders," and the original funds were raised by an issue of £100 shares Among its principal supporters, moreover, were Francis Place, the radical and revolutionary tailor, and Henry (afterwards Lord) Brougham, whose reputation for scrupulous conduct stood none too high "The true Mr Facing-both-ways of Vanity Fair," said Peacock of him How, after a somewhat stormy youth, University College—known originally as London University—gave birth to the now existing university and took on a new name for itself as University College, London, must be read in Sir Philip Magnus's excellent little history, for the dream of its founders, of a University which "expands its portals with equal hospitality to all without distinction," has been realised to the full
